Supplement of

Large-ensemble simulations of the North American and Greenland ice sheets at the Last Glacial Maximum with a coupled atmospheric general circulation–ice sheet model

Fig. S1 Initial conditions and spin-up in stand-alone ice sheet model simulations. (a) ice topography from Tarasov et al. (2012, m) and (b) bedrock topography [m]. Differences of bedrock between 21ka and 0ka in Tarasov et al. (2012) are added on modern bedrock topography. (c) shows the evolution of total ice volume in the 5000 year spin-up with stand-alone Bisicles under spatially uniform surface mass balance and surface air temperature. (d) Correlations of the final ice volume after the spin-up and surface mass balance during the spin-up. In (c) and (d), grey lines and blue dots represent each ensemble member.
Fig. S2 Differences in ice thickness between ice year 5000 and ice year 10000. Results of 6 members out of 16 good simulations are shown.
Fig. S3 Relationship between the changes in the North American ice sheet volume in the first 500 ice years in FAMOUS-BISICLES and each perturbed parameter. Only those ensemble members that satisfy the global temperature constraint are used. Correlation values are displayed above each panel.
Fig. S4 Relationship between the southern extent of North American ice sheet at 5000 ice years in FAMOUS-BISICLES and each perturbed parameter. Only those ensemble members that satisfy the global temperature constraint are used. Correlation values are displayed above each panel. Black dots correspond to the best sixteen members.
Fig. S5 Spatial maps of ice velocity (colour, m/year) and surface elevation (thick black contour, 0 and 3000 m) from sixteen good simulations.
Fig. S6 Relationship between the snowfall rate (kg/m²/day) over the southeastern North America (82.5°W-52.5°W, 35°N-60°N) in FAMOUS-BISICLES and each perturbed parameter. Only those ensemble members that satisfy the global temperature constraint are used. Correlation values are displayed above each panel. Black dots correspond to the best sixteen members.
Fig. S7 Pair plot analysis exploring the combined effects of $f_{\text{snow}}$, $a_{\text{vgr}}$ and $d_{\text{aice}}$ on the ice volume of the North American ice sheet (colours, m SLE). Filled circles outlined in black are the best sixteen members.
