S1. Method details for MidH ECHAM4.6 experiment

In order to force a mid-Holocene climatological SST over the tropical Pacific in the MidH experiment, the ECHAM4.6 is forced with 41-years of modern SSTs, however, the tropical Pacific region (160–275°E; 20°N–20°S) is prescribed with the climatological SST based on the ensemble mean of mid-Holocene simulations from PMIP4 (Fig. S1). First, the year-to-year variability within the tropical Pacific box is suppressed by imposing the 41-year (1979–2019) climatology in the box. This removes the modern-day ENSO variability (as was done in the NoENSO experiment). Next, to shift the climatological SSTs to the mid-Holocene state, we derive the difference in the climatological cycle between the PMIP4 ‘mid-Holocene’ ensemble and CMIP6 ‘Historical’ simulations. The specific models used are shown in Table S1. The difference in the mean climatological annual cycle is then added to the tropical Pacific SSTs.

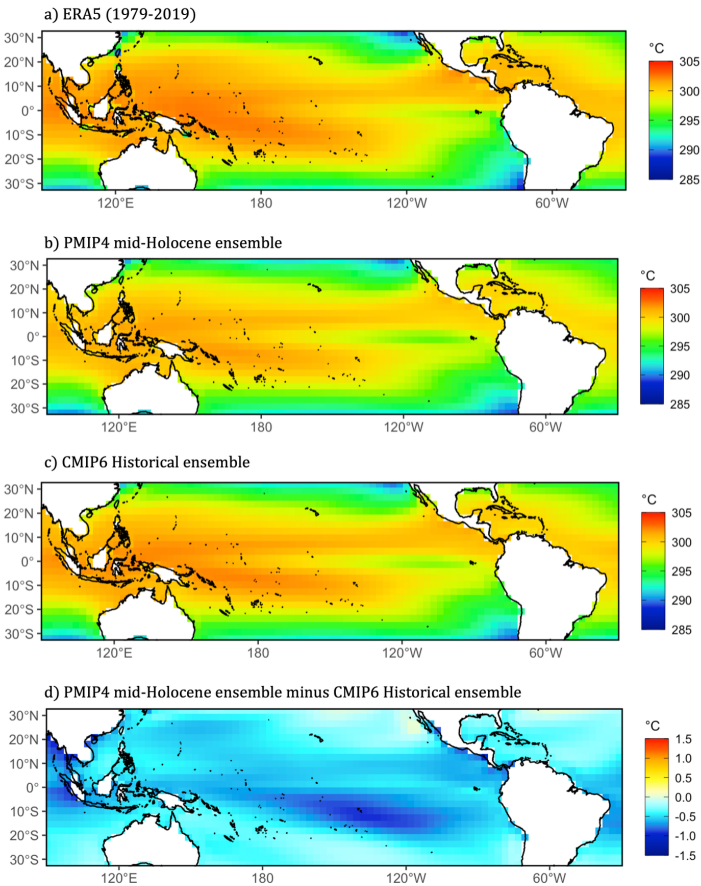

Figure S1: Annual mean climatological SST from (a) ERA5 (1979–2019), (b) PMIP4 mid-Holocene ensemble annual mean SSTs, (c) CMIP6 Historical scenario, and (d) the difference in the ensemble annual mean SSTs, mid-Holocene minus historical (panel b minus panel c).

Table S1: Models used in the calculation of the PMIP4 mid-Holocene ensemble and CMIP6 Historical ensemble (data accessed from <https://aims2.llnl.gov/search>).

S2. $\delta^{18}\text{O}$ proxy records in tropical South America

Most speleothem $\delta^{18}\text{O}$ records in South America are catalogued in the Speleothem Isotopes Synthesis and Analysis (SISAL v2) database (Comas-Bru et al., 2020; Deininger et al., 2019). Speleothem $\delta^{18}\text{O}$ in the SISAL_V2 is presented with respect to the Vienna Pee Dee Belemnite standard (VPDB) and the values are dependent on the mineralogy of the samples, which can differ between aragonite and calcite. Therefore, we convert speleothem $\delta^{18}\text{O}$ values to their dripwater equivalents relative to the Vienna Standard Mean Ocean Water (VSMOW) using a fractionation factor for sample mineralogy (either aragonite or calcite), and the cave site temperatures that are specified by their respective authors. Samples which have unknown, or a mixed mineralogy are excluded from this analysis. The $\delta^{18}\text{O}$ proxy records that fulfil the above requirements are shown in Table S2, along with other $\delta^{18}\text{O}$ records from lake carbonates and ice cores. They are relatively evenly spread across the continent and can provide an adequate depiction of broad spatial patterns.

In Table S2, the mid-Holocene is defined as 5000–7000 BP, the pre-industrial is defined as 850–1850 CE, and the historical period is defined as 1850–2014 CE. The interpretations of mid-Holocene hydroclimate conditions (‘dry’, ‘similar’, and ‘wet’) are taken directly from the respective original publications of each record, following the approach of Prado et al. (2013), such that no additional interpretation is imposed in this study.

There are minor differences in $\delta^{18}\text{O}$ values between the historical (1850–2014 CE) and pre-industrial (850–1850 CE) intervals as multidecadal modes of variability in both the Pacific and Atlantic basins have been shown to influence $\delta^{18}\text{O}$ in precipitation over South America from the pre-industrial onwards (Orrison et al., 2022). Nevertheless, these differences are minor compared to the larger mid-Holocene shifts, indicating that the mid-Holocene interpretation remains robust despite potential modulation by decadal-to-multidecadal variability since the pre-industrial. Furthermore, the amount of tropical warming from 850 CE to present is $\leq 1^\circ\text{C}$, or in terms of $\delta^{18}\text{O}$, less than $-0.24\text{‰}/^\circ\text{C}$ (Kim and O’Neil, 1997). Comparing speleothem $\delta^{18}\text{O}$ in columns 8 to 11 of Table S2 confirms our expectation that $\delta^{18}\text{O}$ over the pre-industrial period is indeed very similar to that over the historical period. Only one record, the Huascaran ice core (which contains a single sample within the historical period), shows a reversal in the direction of change, and several records have limited sample coverage during the historical interval. Hence, to compare the observed and simulated changes in the $\delta^{18}\text{O}$ of precipitation since the mid-Holocene, we use the observed $\delta^{18}\text{O}$ over the pre-industrial period (850–1850 CE) in place of the $\delta^{18}\text{O}$ over the historical period (1850–2014 CE) to take advantage of the much larger sample size available when using the pre-industrial values and to enable us to include the ice core records in our comparison of simulated and observed $\delta^{18}\text{O}$.

65

Table S2: $\delta^{18}O$ records used in this study, and the inferred difference in mid-Holocene precipitation relative to modern day (sixth column). The last four columns show the average $\delta^{18}O$ values from each proxy record for the mid-Holocene and pre-industrial timeframes, the difference between mid-Holocene and pre-industrial, and in the final column, the difference between mid-Holocene and the historical period. The number of sample points used for the historical period is shown in brackets. Locations of each site are shown in Fig. S2.

S3. Performance of ECHAM4.6 model

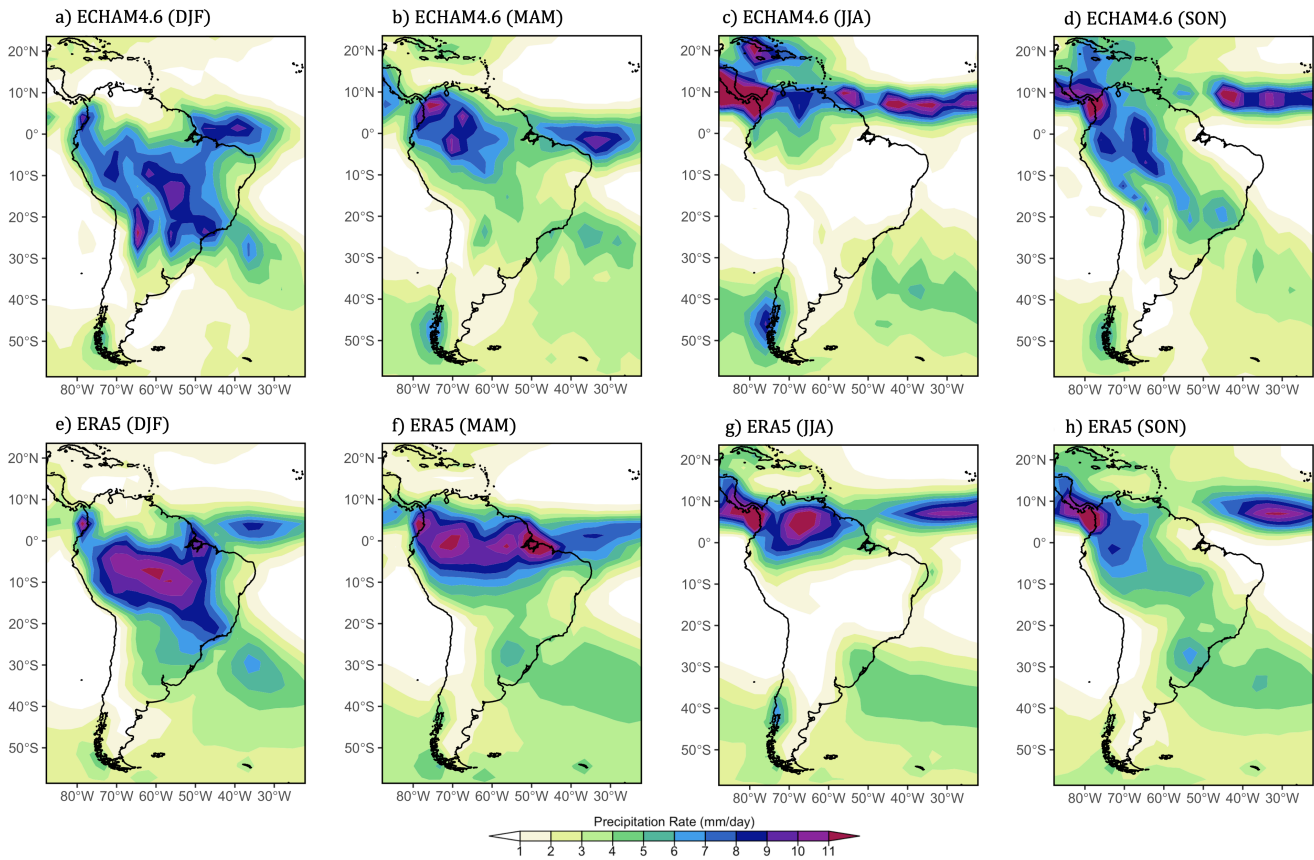

Figure S3: Seasonal precipitation rates over South America (a–d) simulated by ECHAM4.6 with prescribed SSTs over 40-years from 1980–2019 and (e–h) from ERA5 reanalysis (Hersbach et al., 2020) over the same 40-year period. Austral summer (DJF), spring (MAM), winter (JJA) and autumn (SON) climatology is shown in (a/e), (b/f), (c/g) and (d/h) respectively.

100

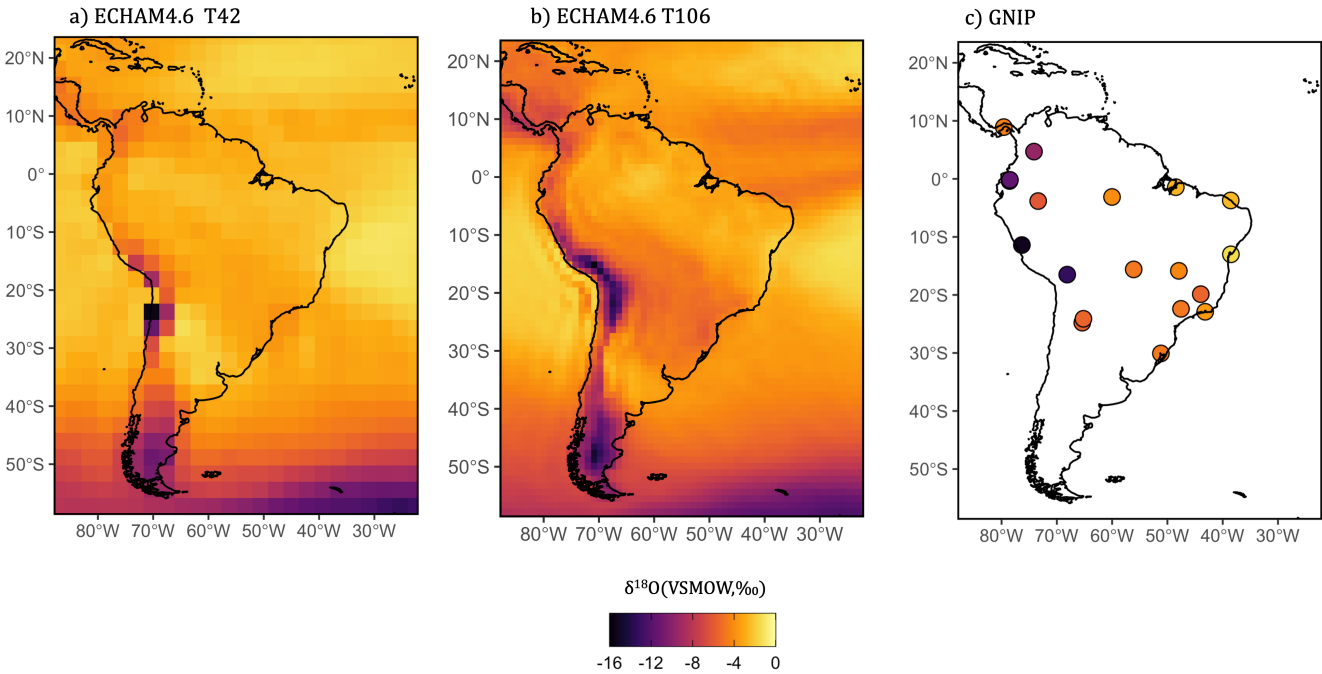

Figure S4: Comparisons of modern day $\delta^{18}O_p$ simulated by ECHAM4.6 at (a) T42 resolution in the current study, and (b) T106 resolution by X. Liu (2022, personal communication), showing a larger inland $\delta^{18}O$ gradient when the model is run with a higher resolution. (c) Measured $\delta^{18}O_p$ from the Global Network of Isotopes in Precipitation (GNIP) stations (IAEA/WMO, 2021).

105

S5. ECHAM4.6 simulation of El Niño/La Niña impact on South America

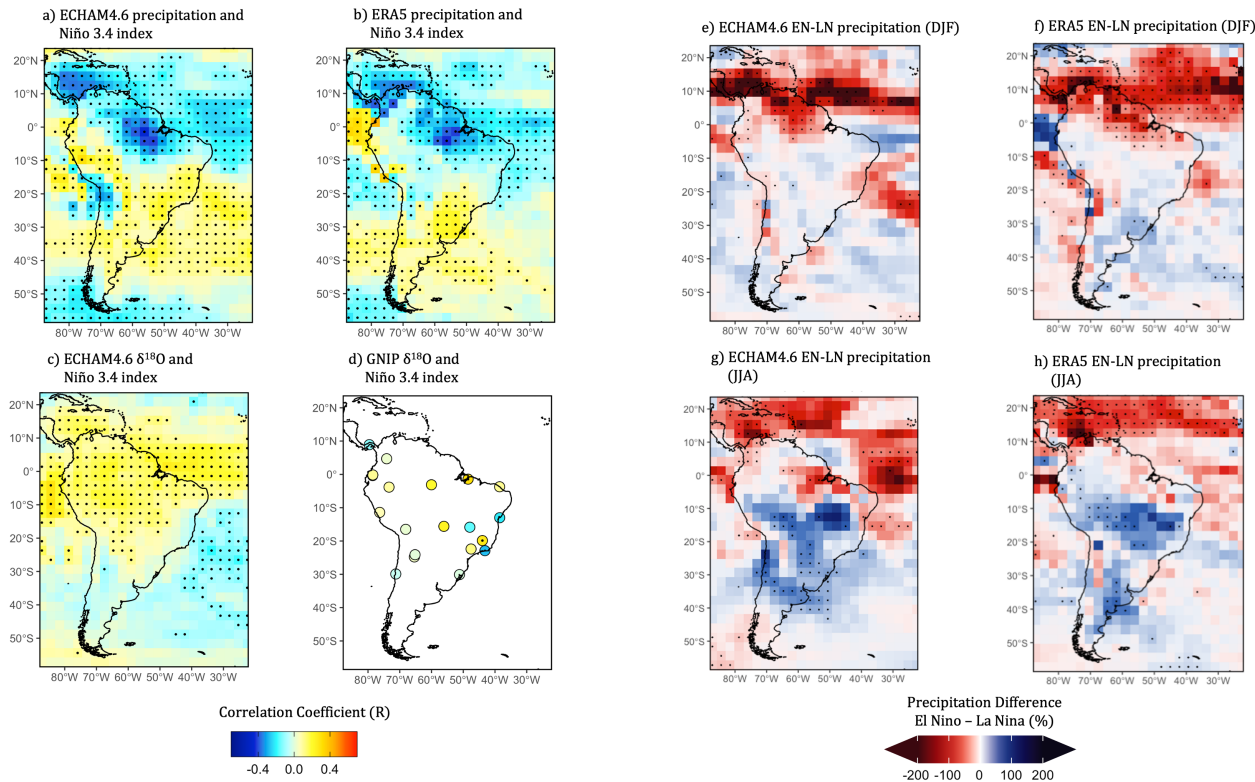

Figure S5: Modern-day ENSO-related anomalies in precipitation (a) simulated by ECHAM4.6 and (b) from ERA5 reanalyses data, found by correlating monthly values of these fields with Niño3.4. The modern-day ENSO-related anomalies are found from the Control simulation. (c) and (d) as in (a) and (b), but for the $\delta^{18}O$ of precipitation. Panel (d) shows the correlations of precipitation $\delta^{18}O$ from GNIP stations with Nino 3.4 index. The difference in precipitation (percentage), calculated as the anomaly between El Niño and La Niña years and normalized by the El Niño composite precipitation, is shown for DJF in (e) ECHAM4.6 Control simulation and (f) ERA5 Reanalysis data; and for JJA in (g) the ECHAM4.6 simulation and (h) ERA5 Reanalysis data. Stippled regions are where the correlation or precipitation difference is significant at a 95% confidence level.

S6. Differences in mid-Holocene simulation with coupled slab ocean model

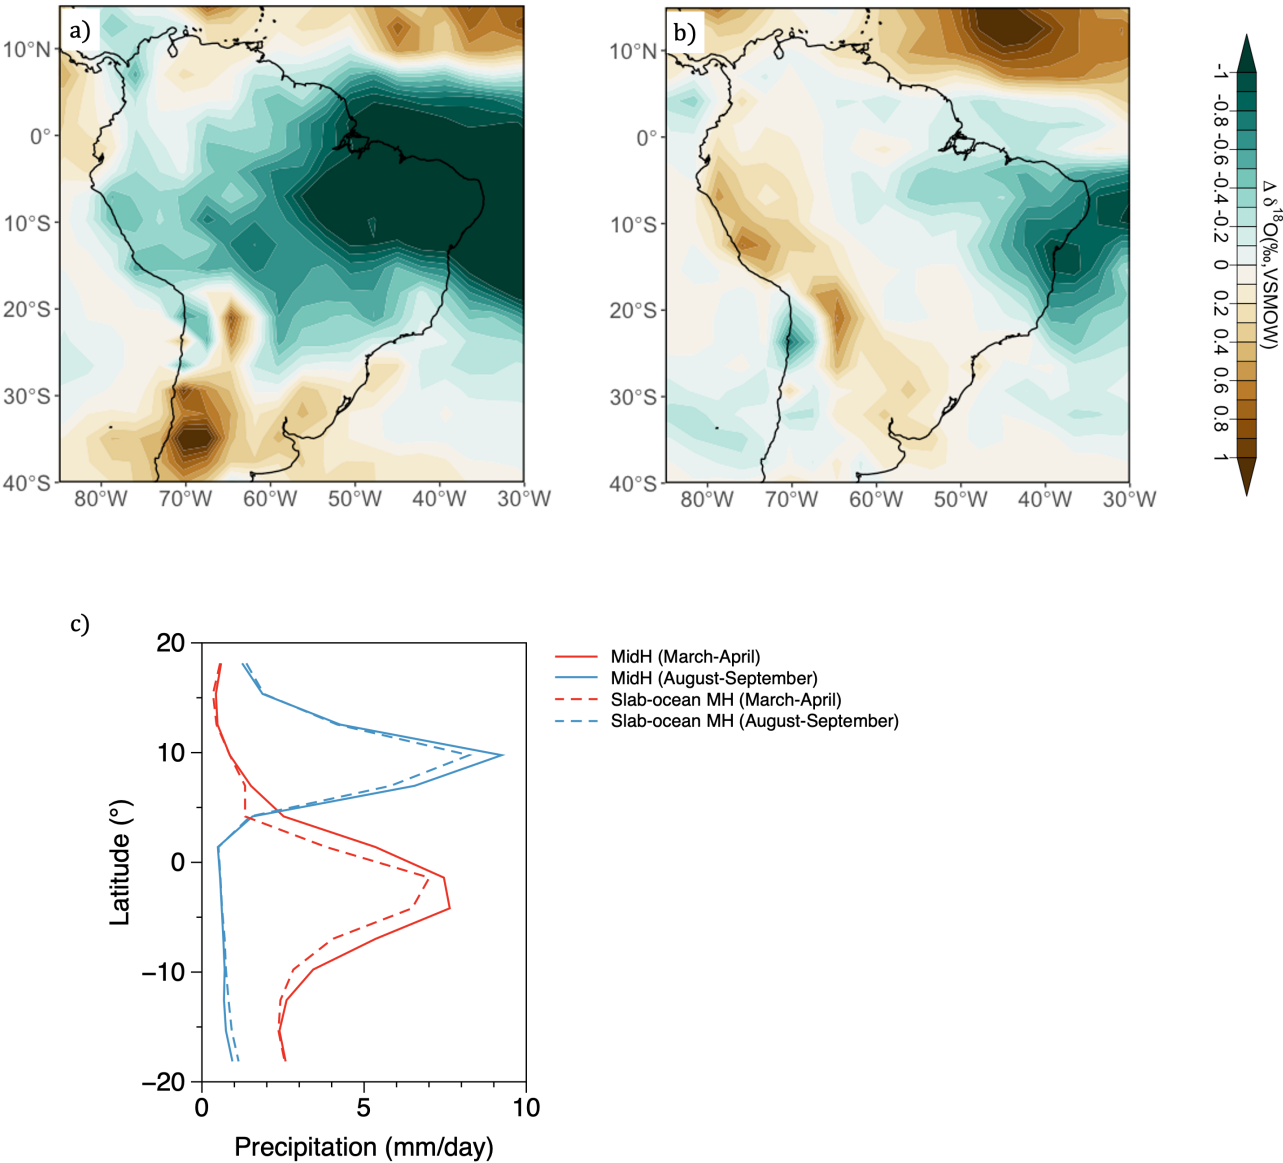

Figure S6: Mid-Holocene minus modern day $\delta^{18}O_p$ simulated by ECHAM4.6 (a) from the experiments in this study using prescribed SSTs (MidH minus Control), and (b) coupled to a slab ocean model (Wong et al., 2023). The simulated ITCZ strength is shown in (c), showing the averaged (between 60°W and 0°) precipitation for March–April (in red) and August–September (in blue) for the mid-Holocene prescribed SST experiment (MidH) in the solid line, and for the mid-Holocene scenario using the same model coupled to a slab-ocean model in dashed line (Slab-ocean MH).
