

Interactive comment on “The 8.2 ka cooling event related to extensive melting of the Greenland Ice Sheet” by H. Ebbesen et al.

H. Ebbesen et al.

Received and published: 15 January 2009

Some of the commented issues from Wolff has been commented from the authors in a reply to Claude Hillaire-Marcel.

Regarding our records, we believe that it is sufficient enough to be used as a good indicator of the period around 8200 cal BP in areas being influenced of changes in the Greenland Ice Sheet. We do not claim to see the event of 8200 cal BP. but we believe that we are looking at a possible causing mechanisms adding to the other well known theories, not excluding them.

Figure 3 will be corrected.
