

## ***Interactive comment on “Heinrich event 1: an example of dynamical ice-sheet reaction to oceanic changes” by J. Álvarez-Solas et al.***

**Anonymous Referee #2**

Received and published: 14 July 2011

I thoroughly enjoyed reading the manuscript by Alvarez-Solas et al. It presents a beautiful new idea in an ice-sheet/ice-shelf modeling framework and provides an interesting twist on our understanding of the dynamics of Heinrich event 1. The paper is well written, but a few minor comments may help to further improve this significant contribution. It is in fact a pity that this paper was not submitted to a higher profile journal.

Minor comments: - the authors discuss a very important positive feedback for Heinrich events. Nowhere in the text is this mentioned. In fact, I think the authors would really gain fame with their results, if they added a little schematic figure, similar to the one attached here.

- I would recommend the authors to discuss figure 4 in more detail. Why is there a 2nd peak/plateau (around years 1200-2000)? What is the dynamics associated with this?

C1071

Why does this occur only for one of the parameter configurations tested?

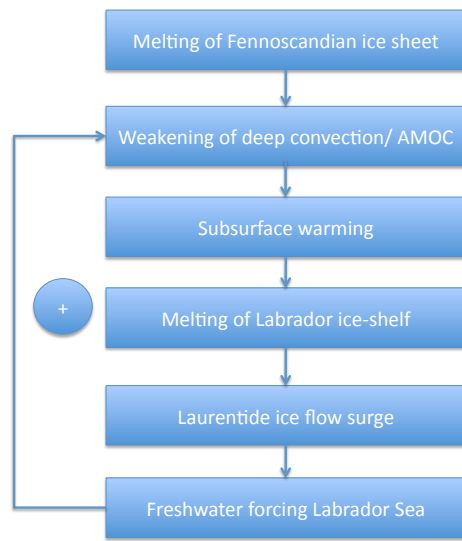

- Please be explicit about some issues regarding the physical consistency in the model set-up.

a. The existence of a Labrador ice-shelf excludes the possibility for Labrador Sea Water formation in reality. However, this effect is not taken into account in the Climber model simulation that is used as a forcing

b. I know that equations (1) and (2) are commonly used in offline-ice sheet model runs. But these equations assume that temperature and precipitation variations are homogeneous across the different ice-sheets, which I think is total nonsense. Stationary wave feedbacks are ignored and the ice-albedo effect is not captured in a physically correct way. I would urge the authors to just state the assumptions made when using this forcing upfront and discuss the caveats.
