

Final author comments

Response to Reviewer 1:

Referee comment 1:

The manuscript submitted by Bouchal et al. is of very high quality. I fully agree with the methods and conclusions. This will be a very useful paper on the mid-Miocene climate change according to floras in the Eastern Mediterranean.

Author's response:

Thank you very much.

Referee comment 2:

I have just two suggestions: - the nearby Çatakbagyaka Langhian pollen flora of (Jiménez-Moreno, 2005 - phd thesis pp. 109 and 212) should be used in the discussion because it contains several mega or mega-mesothermal taxa and 20 to 50% of herbs.

Author's response:

Thank you for drawing our attention to the Çatakbagyaka flora/fauna. The uncertain age of the Çatakbagyaka vertebrate fauna (MN5-MN8) has recently been revised to MN7-8 (see references in our changed manuscript). We refer to this locality in the revised text, considering it roughly coeval with Yeni Eskihişar and mentioning that the increased AP pollen ratios of the Çatakbagyaka flora fit with the general trend observed by us in the Yatagan Basin.

Author's changes in manuscript

The following lines concerning the Çatakbagyaka locality have been inserted in section "3.4 Changes in ratios arboreal to non-arboreal pollen", line 272 in revised manuscript.

.....shows again a higher proportion of arboreal taxa (67%). *Similarly, from the vertebrate locality Çatakbagyaka (revised age MN7+8, 12 km south of the Yatagan Basin) AP percentages range from c. 50% to c. 80% (Jiménez-Moreno, 2005; Mayda et al., 2016; Bouchal et al. 2017; Aiglstorfer et al. 2018).*

and in section "4.4 Detection of Miocene global climatic changes in the terrestrial fossil record", line 458 in revised manuscript.

...Eskihişar pollen assemblage clearly belongs to MN7+8. Here, *and in the nearby locality Çatakbagyaka* woody taxa (*including some warmth-loving taxa*) are again more prominent. Thus, although the correlation.....

Referee comment 3:

The herbs are often under-evaluated in pollen records that causes an significant bias to the ratio 'arboreal taxa/non-arboreal taxa' (see: Favre et al., 2008, Review of Palaeobotany and Palynology, 148, 13-35).

Author's response:

We use the threshold values given by Favre et al. (2008) in the revised manuscript. In

addition, we use the threshold values for local presence of European tree taxa (Lisitsyna et al., 2011 – reference in revised manuscript) to evaluate those pollen floras that are indicated as reflecting “herb-prevalent” environments based on the values given by Favre et al.

Author’s changes in manuscript

The following lines concerning this comment have been inserted under “3.4 Changes in ratios arboreal to non-arboreal pollen”, line 278 in revised manuscript.

*We used the threshold ($AP/NAP = 3.85$) proposed by Favre et al. (2008) to separate between tree- and herb-prevalent environments. This ratio translates into AP percentages of close to 80% to predict reliably tree-prevalent landscapes. As can be seen in Supplementary Material S6, pollen zones 1 and 2 are largely dominated by forested environments. In the upper part of PZ2 (Tinaz, Eskihisar), PZ2/3 and PZ3 (Tinaz) herb-prevalent landscapes are inferred. However, it is noteworthy, that although NAP taxa are more abundant in these pollen zones, AP taxa remain to have fairly high percentages as well (Bouchal et al., 2016, 2017). For example, *Fagus*, *Quercus deciduous* and evergreen type, still are above the threshold values indicative of local tree presence (Lisitsyna et al., 2011). Hence, the opening of the vegetation in the upper parts of PZ2, and in PZ2/3, PZ3 may actually represent a coexistence of forest and open vegetation.*

Referee comment 4:

- Beerling & Royer (2011) and Mai (1995) are not in the Reference list;

Author’s response:

Have been added.

Referee comment 5:

- I do not understand the reference to ‘table S1’ on lines 55 and 407.

Author’s response:

We apologize. This has been misleading. We meant table S1 in the paper of Beerling & Royer, 2011. This has been clarified in the revised manuscript.

Response to Reviewer 2:

Referee comment 1:

Bouchal et al. present a paleobotanic study from middle Miocene Anatolia using different approaches to reconstruct climate changes from existing data of the middle Miocene climate transition, ca. 15-13 Ma. The beauty of the study lies in the combination of three different reconstruction techniques, each with different underlying assumptions.

The authors combine the results of two taxonomical approaches – one relying on the nearest-living-relative principle and the other on biogeography of floras - with leaf physiognomy, which does not rely on taxonomy. The authors conclude that the climate of middle Miocene Anatolia could not have been tropical but would have been fully humid warm temperate. This result is important in the discussion about global latitudinal temperature gradients. The study also reveals increase of herbal vegetation in the mainly forested landscape of Anatolia during the global cooling after the mid-Miocene climate optimum. Moreover, the results of the study

concerning vegetation structure are important in the discussion about the landscape of Anatolia in relation with fossil faunas. Thus, the paper presents an elegant study with interesting results for a wide research spectrum.

Author's response:

Thank you very much.

Referee comment 2:

I would like, however, to give some suggestions that may help reaching that broader audience.

Primarily, the paper needs clear conclusions, which now are missing. I strongly urge the authors to provide them in a separate section.

Author's response:

A concluding paragraph has been added in the revised manuscript.

Author's changes in manuscript:

The following lines have been inserted in section "5. Conclusion" in Line 478 in the revised manuscript.

5. Conclusion

Here we used three proxies to infer climate, palaeoenvironments and biogeographic affinities of three middle Miocene floras of southwestern Anatolia. We showed that the palaeobotanical record resolves transitions from the warm MCO (16.8–14.7 Ma) into the MMCT (14.7–13.9 Ma), and a more pronounced cooling at 13.9–13.8 Ma, mainly expressed in the changing and fluctuating ratios between AP and NAP taxa. Using threshold percentages for main tree taxa, we further show that although NAP values significantly increased during the MMCT, AP taxa remained relatively abundant, signifying the coexistence of forested and open landscapes during this transition. In addition, the biogeographic analysis indicates mainly northern hemispheric biogeographic affinities of the middle Miocene flora of southwestern Anatolia and thus invalidates previous comparisons with tropical environments. Tropical climate conditions are also rejected by the Köppen signatures of the investigated floras and by the CLAMP analysis. Finally, the CLAMP data readily distinguish between strongly seasonal Cs and Cw and fully humid Cf climate types. More combined macrofossil and microfossil studies are needed for the Neogene of Turkey in order to establish a robust framework of terrestrial climate evolution in this important region.

Referee comment 3:

Secondly, the explanation of the Köppen signatures unfortunately hides in the supplementary information. I suggest fitting S2 into a table in the main text.

Author's response:

File S2 has been moved from the supplementary material to the main manuscript as Table 3.

Author's changes in manuscript:

Table 3 and table caption is now included in the main text.

Referee comment 4:

Please, also summarize CLAMP protocols and leaf characteristics (lobbing and tooth form, leaf size, apex form, base form, length-to-width ratio and shape) instead of referring to the website, only.

Author's response:

Additional text concerning this has been included in the final manuscript.

Author's changes in manuscript:

The following lines concerning the CLAMP have been inserted in section "2.4 CLAMP", line 172ff in the revised manuscript.

Referee comment 5:

I suggest plotting the CLAMP results of Tinaz and Eskihisar together in Figure 6. (The separate scores can be found in the supplementary material.)

Author's response:

This has been done in the revised manuscript.

Referee comment 6:

Please explain explicitly what you mean with the question marks to 'marginal???' (line 194) and 'increased summer rainfall???' (line 363).

Author's response:

These were old edits not removed before submission. We apologize for this.

15

16 **Abstract**

17 The middle Miocene climate transition (MMCT) was a phase of global cooling possibly
18 linked to decreasing levels of atmospheric CO₂. The MMCT coincided with the European
19 Mammal Faunal Zone MN6. From this time, important biogeographic links between Anatolia
20 and eastern Africa include the hominid *Kenyapithecus*. Vertebrate fossils suggested mixed
21 open and forested landscapes under (sub)tropical seasonal climates for Anatolia. Here, we
22 infer the palaeoclimate during the MMCT and the succeeding cooling phase for a middle
23 Miocene (14.8–13.2 Ma) intramontane basin in southwestern Anatolia using three
24 palaeobotanical proxies: (i) Köppen signatures based on the nearest-living-relative principle.
25 (ii) Leaf physiognomy analysed with the Climate Leaf Analysis Multivariate Program
26 (CLAMP). (iii) Genus-level biogeographic affinities of fossil floras with modern regions.
27 The three proxies reject tropical [and hot subtropical](#) climates for the MMCT of southwestern
28 Anatolia and instead infer [mild](#) warm temperate C climates. Köppen signatures reject
29 summer-dry Cs climates but cannot discriminate between fully humid Cf and winter-dry Cw;
30 CLAMP reconstructs Cf climate based on the low X3.wet/X3.dry ratio. Additionally, we
31 assess whether the palaeobotanical record does resolve transitions from the warm Miocene
32 Climatic Optimum (MCO, 16.8–14.7 Ma) into the MMCT (14.7–13.9 Ma), and a more
33 pronounced cooling at 13.9–13.8 Ma, as reconstructed from benthic stable isotope data. For
34 southwestern Anatolia, we find that arboreal taxa predominate in MCO floras (MN5),
35 whereas in MMCT floras (MN6) abundances of arboreal and non-arboreal elements strongly
36 fluctuate indicating higher structural complexity of the vegetation. Our data show a distinct
37 pollen zone between MN6 and MN7+8 dominated by herbaceous taxa. The boundary MN6
38 and MN7+8, roughly corresponding to a first abrupt cooling at 13.9–13.8 Ma, [might be](#)
39 associated with this herb-rich pollen zone.

44 1 Introduction

45 The middle Miocene (15.97–11.63 Ma, ICS-chart 2017/02, Cohen, 2013) is characterized by
46 a warm phase lasting until ca. 15 Ma that was followed by a gradual cooling and the
47 restoration of a major Antarctic ice sheet and first northern hemispheric glaciations (Holbourn
48 et al., 2014). It has been suggested that the final closure of the Mediterranean gateway
49 connecting the Mediterranean with the Indian Ocean and the resulting changes in ocean
50 circulation might have been one of the reasons for the final expansion of the East Antarctic
51 ice sheet around 14.8 Ma (Flower & Kennett, 1993). During the middle Miocene climate
52 transition (MMCT) at 14.7 to 13.8 Ma a drop of sea surface temperatures of 6–7°C occurred
53 (Shevenell et al., 2004). At the same time, different proxies to reconstruct atmospheric CO₂
54 levels for the Miocene Climatic Optimum (MCO), MMCT, and the succeeding more
55 pronounced cooling, do not concur (Beerling & Royer, 2011). Specifically, stable isotope data
56 from phytoplankton infer stable CO₂ levels for the Neogene, with minor fluctuations (MCO,
57 227–327 ppm, MMCT, 265–300 ppm; [see table S1 of Beerling & Royer, 2011](#)), while
58 stomata densities from fossil leaves suggest a pronounced drop of CO₂ after the MCO ([see](#)
59 [table S 1 of Beerling & Royer, 2011](#)).

60 The European Mammal Faunal Zone MN6 (14.8–13.8 Ma; Neubauer et al., 2015) coincides
61 with the MMCT. From this period world-famous vertebrate faunas are known from western
62 Anatolia (e.g. Andrews & Tobien, 1977; Mayda et al., 2015) including the hominoids
63 *Griphopithecus alpani* in Çandır and Paşalar, and *Kenyapithecus kizili* in Paşalar (Stringer &
64 Andrews, 2011). Geraads et al. (2003) investigated the depositional environment and large
65 mammal fauna of Çandır close to Ankara and inferred open landscapes for this locality.
66 Bernor et al. (1979, p. 86) analysed community structure of Turkish and European middle
67 Miocene faunas and suggested that “*faunas adapted to woodland conditions were present ...*
68 *at localities such as Paşalar and Yeni Eskihisar [MN7+8]*” while the “*Çandır fauna has a*
69 *community structure more suggestive of closed woodland conditions*”. This interpretation is

74 the exact opposite of that by Geraads et al. (2003). Recent investigations using carnivore guild
75 structure suggest a “*mixed environment between tropical forest and open savannah*
76 *landscapes*” for Çandır and Paşalar (Mayda et al., 2015). Strömberg et al. (2007) investigated
77 phytoliths (plant silica bodies) from early to late Miocene deposits of Turkey and suggested
78 that open, grass-dominated habitats had become common in Turkey and adjacent areas by the
79 early Miocene (c. 20 Ma). In contrast, Kayseri-Özer (2017) using ‘integrated plant record’
80 (IPR) analysis (Kovar-Eder et al., 2008) suggested that various forest types covered most of
81 western and Central Anatolia during the middle Miocene (*broad-leaved evergreen* and *mixed*
82 *mesophytic forests* and ecotones between these forests).

83 Here we use a large data set from recently published macrofossils and pollen, spores and cysts
84 from a well-dated middle Miocene basin in western Anatolia to infer palaeoclimate and
85 palaeoenvironments using three palaeobotanical proxies: climate affinity of modern analogues
86 (‘nearest living relatives’; taxon-based approach), leaf physiognomy (a-taxonomic), and
87 biogeographic affiliation of plant communities (also taxon-based). The following research
88 questions are addressed: How do the three approaches resolve local climate conditions of
89 Anatolia during a phase of global cooling, ca. 15–13 million years ago? Do different proxies
90 agree on climate inference? Where do modern climates occur that correspond to middle
91 Miocene climates of western Anatolia? Can the palaeobotanical record resolve transitions
92 between MCO, MMCT, and the succeeding more pronounced cooling during the middle
93 Miocene?

94

95 **2 Material and methods**

96 **2.1 Geological setting**

97 The Yatağan Basin is a southeast trending graben (50 km long, 15 km wide) in the province
98 of Muğla, southwestern Turkey (Fig. 1). The Neogene basin fill is up to 600 m thick and
99 divided into the Eskihisar Formation (early to middle Miocene), the Yatağan Formation (late

100 Miocene to early Pliocene), and the Milet Formation (middle to late Pliocene; Alçiçek, 2010).
101 The Eskişehir Formation comprises the Turgut Member (reddened alluvial-fan deposits
102 followed by fluvial deposits and lignites) and the Sekköy Member (fossiliferous limnic
103 marls and limestones); all economically exploited lignite seams of the Yatağan Basin are
104 confined to the transition zone of these two members (Atalay, 1980; Becker-Platen, 1970).
105 For the present study, we investigated the palaeobotanical content (pollen and plant
106 macrofossils) of the upper Turgut and the Sekköy members exposed at the lignite mines of
107 Eskişehir, Salihpaşalar, and Tınaz (Fig. 1.2). The age of the investigated sediments is well
108 constrained by mammal fossils (Eskişehir lignite gallery locality, MN6, *Gomphotherium*
109 *angustidens* Cuvier 1817, *Percrocuta miocenica* Pavlov et Thenius 1965, Bouchal et al.,
110 2017; Yeni Eskişehir vertebrate locality, MN 7/8, The NOW Community, 2018), and by
111 radiometric dates from the upper Sekköy Member (13.2 Ma \pm 0.35, Becker-Platen et al.,
112 1977). Hence, the investigated pollen zones (PZ) 1, 2, 2/3, and the Yeni Eskişehir pollen
113 assemblage represent the Neogene mammal zones MN6 and MN7+8, 14.8–13.2 Ma;
114 Neubauer et al., 2015). The layers from which most of the leaf fossils originate correspond to
115 PZ 2. A ~20 m section comprised of limestone and clayey limestone between PZ 2/3 and the
116 Yeni Eskişehir assemblage is barren of palynological content (Fig. 2).

117

118 **2.2 Plant material**

119 The investigated plant material comprises roughly 1800 macrofossils (mainly leaf fossils)
120 collected between 2010 and 2017. Macrofossils represent 77 taxa, of which five belong to
121 gymnosperms and 72 to angiosperms. Pollen, spores and cysts from five pollen zones (Fig. 2)
122 represent 182 taxa, of which one is a fungus, 9 are algae, 17 moss or fern allies spores, 15
123 gymnosperms, and 140 angiosperms ([Supplementary Material S1](#); for taxonomic descriptions
124 of the plant taxa see Yavuz-Işık et al., 2011; Bouchal et al., 2016, 2017; Bouchal, in press;
125 Güner et al., 2017).

126

127 2.3 Köppen signatures

128 Fossil taxa that are resolved to genus or sectional level were represented by extant members
129 of the genera and sections as modern analogues. First, for accepted taxa (IPNI,
130 <http://www.ipni.org/index.html>; most recent regional floras and monographs) their
131 distribution ranges were determined. Then, 26 Köppen-Geiger climate types (see [Table 3](#) for
132 detailed explanation of Köppen-Geiger climate types, and Kottek et al., 2006; Peel et al.,
133 2007; Rubel et al., 2017; [Global_1986-2010_KG_5m.kmz](#)) were mapped on modern
134 distribution ranges using Google Earth to establish 'Köppen signatures' (Denk et al. 2013) for
135 each modern analogue. Representation of different climate types was first scored for each
136 species within a genus as present (1)/absent (0). To summarize preferences for climate types
137 of all modern analogues, we used an implicit weighting scheme to discriminate between
138 modern analogues that are highly decisive (climatically constrained) vs. those that can be
139 found in many climate zones. The sum of each modern species' Köppen signature is always
140 one. For example, *Tilia chingiana* is present in two Köppen-Geiger climate types, *Cfa* and
141 *Cfb*, which count as 0.5 for each type, while *Tilia americana* is present in ten Köppen-Geiger
142 climate types (*As*, *Aw*, *Cfa*, *Cfb*, *Dfa*, *Dfb*, *Cwa*, *Cwb*, *BSk*, *BWh*), all counting as 0.1. The
143 Köppen signature of a genus or section, the modern analogue of a fossil taxon, is the sum of
144 its species' Köppen signatures for each climate type divided by the total number of scored
145 species for this genus. By this, the percentage representation of each Köppen-Geiger climate
146 type was determined for a genus/ section. In case of *Tilia*, the distribution ranges of 26 species
147 resulted in a genus Köppen signature as follows: *Cfa*, 22.1%, *Cfb*, 14.7%, *Cwa*, 19.9%, *Cwb*,
148 9.1%, *Dfb*, 5.7%, for the five most common climate types. Fig. 3.1 shows all climate types
149 realized in genus *Tilia*; Fig. 3.2 shows that the genus occurs predominantly in *Cf* and *Cw*
150 Köppen-Geiger climate types and that tropical and desert climates are nearly absent (see

Johannes Bouchal 17.8.18 21:47
Gelöscht: Supplementary Material S2

Authors 3.9.18 14:25
Gelöscht: .

153 [Supplementary Material S3](#) for genus-level scoring of Köppen-Geiger climate types for all
154 plant taxa encountered in the Yatağan basin fossil assemblages).
155 For taxa that are resolved to family-level only, mainly pollen taxa of herbaceous and a few
156 woody angiosperm groups, the distributions of extant members of the family were combined
157 into a general family distribution range and the corresponding Köppen-Geiger climate types
158 determined.
159 Genus-level Köppen-Geiger signals were used to account for possible niche evolution within
160 lineages/ species groups of a genus. For example, modern species of *Quercus* section *Ilex* are
161 typical members of sclerophyllous, evergreen Mediterranean forest and shrubland vegetation
162 thriving under a *Cs* (summer-dry warm temperate) climate in western Eurasia and [to the south](#)
163 [of the eastern Hindu Kush and Karakorum ranges](#), but also occur in humid, mesophytic
164 forests from Afghanistan to East Asia (*Cf* and *Cw* climates). To account for this climate niche
165 variability, all species of sect. *Ilex* were scored for the general Köppen signature of sect. *Ilex*.
166 Hence, the entire section was used as modern analogue, the nearest living relative (NLR), for
167 several fossil species of *Quercus* sect. *Ilex*.

168

169 2.4 CLAMP

170 We inferred quantitative palaeoclimate parameters for the three Yatağan Basin floras using
171 the Climate Leaf Analysis Multivariate Program (CLAMP) (Yang et al., 2011). CLAMP
172 makes use of the relationship between leaf physiognomy [of dicotyledonous flowering plants](#)
173 and climate and, hence, is a non-taxonomic approach to palaeoclimate inference (Spicer,
174 2008). [CLAMP calibrates the numerical relations between leaf physiognomy of woody](#)
175 [dicots and meteorological parameters in modern terrestrial environments. With this](#)
176 [calibration, past climatic data can be determined from leaf fossil assemblages if the](#)
177 [sampling of the fossil assemblage represents well the characteristics of the living source](#)
178 [vegetation \(http://clamp.ibcas.ac.cn\).](#) Modern and fossil leaf physiognomic data are

Authors 3.9.18 11:51

Johannes Bouchal 17.8.18 21:49
Gelösch: 6

217 assemblage (using genus-level NLR). The sum of *Cf*, *Df*, *Cw* and *Dw* climates amounted to
218 60–70% in all assemblages (highest scores in macrofossil assemblages).
219 Overall, the best represented Köppen-Geiger climate types when using genus-level NLR were
220 *Cfa* (warm temperate, fully humid, hot summer), followed by *Cfb* (warm temperate, fully
221 humid, warm summer), *Cwa* (warm temperate, winter-dry, hot summer), and *Cwb* (warm
222 temperate, winter-dry, warm summer). Summer-dry *Cs* climates were represented by 9–13%
223 and arid (generally dry) *B* climates by 6–11% (Table 3, Supplementary Materials, S4).
224 Tropical (equatorial) climates (*A*) are represented by 9–11% in older assemblages, and 7–8%
225 in the two youngest assemblages (PZ 2/3 and Yeni Eskihisar). Of 1555 modern species used
226 to inform the Köppen signatures of the NLRs for the fossil taxa, 119 show marginal range
227 extensions into *Af* climate, 168 into *Am* (heavy monsoon), 85 into *As*, and 295 into *Aw*
228 (Supplementary Material S2). Taxa extending in tropical climates are mainly species of *Pinus*,
229 *Celtis*, *Smilax*, and *Viburnum*, *Quercus* sections *Quercus* and *Lobatae*, Juglandaceae
230 subfamily Engelhardioideae, Oleaceae, and Sapotaceae. Exclusion of Köppen-Geiger climate
231 signals extracted from cosmopolitan and/or gymnospermous taxa did not change the general
232 trends (Supplementary Material S5).

234 3.2 CLAMP

235 Sixty-three morphotypes were scored for Eskihisar (Fig. 6; see Supplementary Material S3 for
236 score sheets and other reconstructed climate parameters). Inferred values for mean annual
237 temperature (MAT) were (11.2–) 12.6 (–14) °C, for coldest month mean temperature
238 (CMMT) (0.3–) 2.3 (–4.4) °C, and for the three wettest months (X3.wet) (410–) 666 (–936)
239 mm and for the three driest months (X3.dry) (148–) 204 (–262) mm. The ratio X3.wet/X3.dry
240 was between 2.9 and 3.6. For Tınaz, the reconstructed MAT was (12.3–) 13.8 (–15.2) °C,
241 CMMT (1.5–) 3.6 (–5.6) °C, X3.wet (420–) 700 (–980) mm, and X3.dry (146–) 205 (–260)
242 mm. The ratio X3.wet/X3.dry was between 2.9 and 3.8. Values for Salihpaşalar are not

251 3.3 Genus level biogeography

252 The genus-level biogeographic analysis of the four Yatağan Basin floras ranging in age from
253 14.8 to 13.2 Ma (MN6 into MN7+8; Table 1) shows that closest biogeographic relationships
254 are with the modern East Asian flora (54 of 59 taxa shared with East Asia), 48 and 44 genera
255 are shared with the modern western Eurasian and eastern North American floras, respectively.
256 Among modern tropical floras, closest relationships are with South America (21), followed by
257 Africa (16) and northern/ north-eastern Australia (13). Most taxa extending to tropical regions
258 are cosmopolitan (e.g. *Euphorbia*, *Drosera*, *Phragmites*), hence, of little discriminative
259 power. This is also true for higher taxa such as Polygalaceae and Valerianoideae. The fossil
260 species *Smilax miohavanensis* belongs to a subtropical-tropical clade of extant species (Denk
261 et al., 2015) and is the only member of this group in Eurasia; it has its last occurrence in the
262 middle Miocene floras of the Yatağan Basin. Overall, the dominating biogeographic signal is
263 a northern hemispheric one.

Johannes Bouchal 30.8.18 22:53
Gelöscht: /

265 3.4 Changes in ratios arboreal to non-arboreal pollen

266 Ratios of arboreal pollen (AP) to non-arboreal pollen (NAP) change considerably among and
267 within pollen zones of the Yatağan Basin assemblages (Table 2, [Supplementary Material S6](#)).
268 Pollen zone 1 (main lignite seam) consistently has high percentages of AP (94–70%). In
269 contrast, AP percentage values fluctuate throughout pollen zone 2, with values from 89 to 29.
270 Pollen zone 2-3, only covered in the Tınaz section, records AP percentages of 50 to 19.
271 Above, the MN7+8 assemblage of Yeni Eskihsar shows again a higher proportion of arboreal
272 taxa (67%). [Similarly, from the vertebrate locality Çatakbağyaka \(revised age MN7+8, 12 km](#)

Johannes Bouchal 17.8.18 21:50
Gelöscht: 7

276 south of the Yatağan Basin) AP percentages range from c. 50% to c. 80% (Jiménez-Moreno,
277 2005; Mayda et al., 2016; Bouchal et al. 2017; Aiglstorfer et al. 2018).
278 We used the threshold (AP/NAP = 3.85) proposed by Favre et al. (2008) to separate between
279 tree- and herb-prevalent environments. This ratio translates into AP percentages of close to
280 80% to predict reliably tree-prevalent landscapes. As can be seen in Supplementary Material
281 S6, pollen zones 1 and 2 are largely dominated by forested environments. In the upper part of
282 PZ2 (Tınaz, Eskişehir), PZ2/3 and PZ3 (Tınaz) herb-prevalent landscapes are inferred.
283 However, it is noteworthy, that although NAP taxa are more abundant in these pollen zones,
284 AP taxa remain to have fairly high percentages as well (Bouchal et al., 2016, 2017). For
285 example, *Fagus*, *Quercus* deciduous and evergreen type, still are above the threshold values
286 indicative of local tree presence (Lisitsyna et al., 2011). Hence, the opening of the vegetation
287 in the upper parts of PZ2, and in PZ2/3, PZ3 may actually represent a coexistence of forest
288 and open vegetation.

290 **4 Discussion**

291 **4.1 Climate inference using Köppen signatures and CLAMP**

292 Using Köppen signatures, we made a semi-quantitative reconstruction of the palaeoclimate of
293 the Yatağan Basin during the middle Miocene. All Köppen signatures used here rely on the
294 nearest-living-relative principle (Denk et al., 2013). Such approaches are prone to error
295 because niche evolution may have occurred in lineages, the morphologically nearest living
296 relatives (NLRs), a species or group of morphologically similar species, of fossil taxa may
297 have different niches, and the shift is difficult to quantify (Ackerly, 2004; Grimm & Potts,
298 2016; Denk et al., 2017). Hence, we opted against applying quantitative NLR methods and
299 determined Köppen signatures for fossil taxa using information from all extant species of a
300 genus used as NLR to avoid bias from undetected niche shifts.

302 | It is important to keep climatic niche shift in mind when using NLR based approaches to
303 palaeoclimate inference and interpreting their results (cf. Grimm & Potts, 2016; Denk et al.,
304 2017). In our dataset of 1555 modern species, 295 also occur in tropical *Aw* climates. Most of
305 them belong to clades (monophyletic sections, genera, families) that occur in a wide range of
306 climate types (e.g. Amaranthaceae, *Celtis*, white and red oaks). Others, such as *Engelhardia*
307 are usually interpreted as tropical-subtropical evergreen element (Kvaček, 2007) based on the
308 distribution range of the extant genera of the comprising subfamily, the Engelhardioideae.
309 However, '*Engelhardia*' of the western Eurasian Cenozoic belongs to its own (extinct)
310 section or genus *Palaeocarya* (Kvaček, 2007) with a stratigraphic range from Eocene to
311 Pliocene. Pollen, foliage, and reproductive structures of fossil material clearly belong to
312 subfamily Engelhardioideae but cannot be assigned to just a single modern genus *Engelhardia*
313 (tropical Southeast Asia). Instead the fossil-taxon is a mosaic taxon having characteristics of
314 both American and Asian members of the subfamily. Kvaček (2007) noted that the fossil
315 genus/subgenus flourished in subtropical climates during the Eocene but in distinctly
316 temperate climates with coldest month mean temperatures close to the freezing point in the
317 Neogene, in stark contrast to the surviving four, likely relict genera of the Engelhardioideae.
318 Hence, this extinct lineage of Engelhardioideae is not well represented by a single or the
319 combination of all extant genera and their constituent species. Similarly, representatives of
320 *Smilax havanensis* and allied species are part of a New World clade with most species
321 occurring in tropical climates. However, the single Old World member of the clade, the fossil
322 species *S. miohavanensis*, is known from early to middle Miocene strata of Anatolia and
323 Central Europe (Denk et al., 2015). This fossil species formed part of plant assemblages that
324 rule out tropical climates. In this case, inferring palaeoclimate from extant distribution data
325 only inevitably will produce noise to the climatic signal.
326 Overall, the most common Köppen-Geiger climate types of NLR taxa of the Yatağan floras
327 were warm temperate *C* types, and among *C* types fully humid *Cf* climates were better

329 | represented than more seasonal C_w and C_s types (Fig. 5; [Supplementary Material S4](#)). C_s
330 | types played only a minor role; however, there was no clear preference of C_f over C_w
331 | climates in the representation of Köppen-Geiger climate types. Removing azonal taxa, or taxa
332 | commonly associated with higher elevations (conifers) did not affect the general signal.
333 | In contrast, CLAMP is not based on NLR and hence not potentially biased by taxonomic
334 | error. Its combination with the Köppen signature analysis provides a powerful tool for climate
335 | inference and to discern between seasonal C_w (winter dry) and C_s (summer dry) and fully
336 | humid C_f climates can be made. Specifically, the ratio of the wettest and the driest month
337 | clearly distinguishes strongly seasonal summer rain (monsoon) climates (C_w ; precipitation
338 | wettest month $> 10x$ precipitation driest month, [$P_{\text{dry}/\text{sdry}} < P_{\text{wet}/\text{wwet}}/10$]; Peel et al., 2007)
339 | from weakly seasonal, fully humid climates (C_f ; precipitation wettest month $\ll 10x$
340 | precipitation driest month). Precipitation values for X3.wet and X3.dry inferred by CLAMP,
341 | and the ratio between these ranges being between 2.9 and 3.8 thus largely rules out a C_w
342 | climate (X3.wet and X3.dry are closely correlated to $P_{\text{dry}/\text{wet}}$). In conjunction with the Köppen
343 | signature results ruling out summer-dry conditions, the CLAMP precipitation and temperature
344 | estimates point towards cold subtropical to mild temperate C_{fa} climates at the margin to fully
345 | temperate C_{fb} climates.

346

347 **4.2 Comparison to palaeoclimate and palaeoenvironment inferences from other proxies**

348 | A further refinement of previous climate and vegetation inferences can be made regarding the
349 | distinction between tropical ($T_{\text{min}} \equiv \text{CMMT} \geq 18 \text{ }^\circ\text{C}$), subtropical ([8–12](#) months with $T \geq 10^\circ$
350 | C ; $\sim \text{MAT}$ [12–18](#) $^\circ\text{C}$, and $\text{CMMT} \leq 18 \text{ }^\circ\text{C}$) and temperate climates. CLAMP consistently
351 | resolves $\text{MAT} < 18 \text{ }^\circ\text{C}$ and $\text{CMMT} < 6 \text{ }^\circ\text{C}$ for the localities Eskihisar and Tınaz, and this
352 | agrees with the results from Köppen signatures and a previous qualitative assessment of
353 | palaeoenvironments in the Yatağan Basin (Güner et al., 2017). Both these results, rejecting
354 | strongly seasonal C_w climates, summer dry C_s , and tropical A climates (at least for non-

Johannes Bouchal 17.8.18 21:49

Gelöscht: 5

Authors 3.9.18 12:10

Gelöscht: of

357 coastal areas) for the middle Miocene of western Anatolia, have implications for the
358 reconstruction of palaeoenvironments of famous vertebrate localities in Anatolia that are
359 assigned to MN6. The $\delta^{13}\text{C}$ composition from fossil tooth enamel at Paşalar, western
360 Anatolia, MN6, indicates that animals were feeding on C_3 vegetation (Quade et al., 1995).
361 The palaeoenvironment for this locality was determined as closer to Indian subtropical
362 forests, with seasonal summer rainfalls (i.e. warm *Cwa* climates), semi-deciduous forest and
363 dense ground vegetation (Stringer & Andrews, 2011; Mayda et al., 2015). Using carnivore
364 guild structures Morlo et al. (2010) inferred open (Serengeti type, *Aw* climate) landscapes for
365 the Central Anatolian MN6 vertebrate locality Çandır. Also, the NOW database
366 (<http://www.helsinki.fi/science/now/>; The NOW Community, 2018) refers to Çandır as more
367 open (“woodland biome”, “open vegetation structure”, “grassland with mosaic of forests”)
368 and to Paşalar as more forested landscapes (“subtropical”, “closed vegetation structure”,
369 “semi-deciduous forests”). Bernor et al. (1979) using community structure of vertebrate
370 faunas inferred densely wooded environments for Çandır. In a later study based on a
371 taxonomic revision of carnivores, Mayda et al. (2015) proposed a mixed environment
372 between tropical forests and open savannah landscapes for Çandır. It is important to note that
373 these carnivore guild structure studies used only two modern calibration faunas to estimate
374 palaeoenvironments, one tropical rainforest fauna in Guyana, and one savannah (tropical)
375 fauna in the Serengeti (Morlo et al., 2010). Thus, using this proxy, only two environments can
376 be reconstructed, tropical savannah or rainforest.

377 Our plant-proxy based climate reconstruction unambiguously rejects a tropical climate for the
378 middle Miocene Yatağan Basin and major biogeographic patterns strongly suggest northern
379 hemispheric affinities. Similar environmental conditions as reconstructed in our study have
380 been inferred for most of western Anatolia during the late early and middle Miocene
381 (Kayseri-Özer, 2017). Most proxies currently used to infer climate and vegetation in western
382 Anatolia during the middle Miocene (carnivore guild structures, vertebrate community

383 structure, plant functional types, plant macrofossils, pollen and spores; Mayda et al., 2015,
384 2016; Kayseri-Özer, 2017; Güner et al., 2017; Bouchal et al. 2016, 2017; Bouchal, 2018)
385 clearly infer forested vegetation with varying contributions of open vegetation. In contrast,
386 Strömberg et al. (2007) found that “*all Miocene phytolith assemblages point to relatively open*
387 *vegetation, such as savanna or open woodland dominated by open-habitat grasses, or a*
388 *mixture of grassland and wooded areas*”. This result may be biased (see Jokela, 2015, p. 44)
389 and increased diversity of grass types in the phytolith record may not necessarily indicate the
390 presence of widespread open, grass-dominated landscapes.

391

392 4.3 Modern climate analogues

393 The inferred climate for the middle Miocene Yatağan Basin plant assemblages is
394 characterized by MAT 11–15 °C, coldest month mean temperature (CMMT) 0–6 °C, MAP
395 ca. 1000–2000 mm, and ratios of X3.wet/X3.dry 2.9–3.8. A non-exhaustive search for climate
396 stations with this combination of climate parameters ([Supplementary Material S7](#)) identified a
397 single closest match, Pacific central Honshu of Japan. X3.wet/X3.dry ratios and MAT are
398 similar to the upper limits of the ranges reconstructed for the middle Miocene Yatağan Basin.
399 East Asian *Cf* climates are generally characterized by distinct summer rain maxima. The
400 modern vegetation of Japan is home to many plant taxa that are currently absent from western
401 Eurasia but were abundant in Neogene plant assemblages of western Eurasia (e.g.
402 *Cephalotaxus*, *Cryptomeria*, *Torreya*, *Alangium*, *Camellia*, *Castanopsis*, *Cercidiphyllum*,
403 *Daphniphyllum*, *Eurya*, *Fatsia*; Mai, 1995; Miyawaki, 1984; see also Milne, 2004). These
404 taxa require warm and humid equable climates.

Johannes Bouchal 17.8.18 21:50

Gelöscht: 8

405 A further close match is the area from northern Turkey via Georgia to northern Iran, the
406 Euxinian-Hyrcanian region ([Supplementary Material S7](#)). Climates at the transition between
407 *Csa* and *Cfa/b* of the region north of Istanbul have up to 1166 mm MAP (Ustaoglu, 2012) and
408 other climate parameters in this area match the Miocene climate of southwestern Turkey

Johannes Bouchal 17.8.18 21:50

Gelöscht: 8

413 inferred by CLAMP. Towards the humid north-eastern part of Turkey, X3.wet/X3.dry ratios
414 are lower (2.4 for Rize, Hopa and Poti and Kobuleti in adjacent western Georgia). Further to
415 the east, south of the Caspian Sea, Rasht and Kiashahr have *Cfa* and borderline *Csa* to *Cfa*
416 climates with slightly more pronounced seasonality than the reconstructed climate for the
417 Miocene of southwestern Turkey (X3.wet/X3.dry ratios 4.4 and 4.2). In contrast,
418 X3.wet/X3.dry ratios in modern Mediterranean western and southwestern Turkey amount to
419 25 (Izmir) and 21.8 (Muğla, Yatağan Basin). It is noteworthy that modern *Cf* climates of the
420 Euxinian-Hyrcanian region differ markedly from those of the Pacific part of Honshu by their
421 summer minima in rainfall (Supplementary Material S7). This feature indicates a (weak)
422 Mediterranean influence in this region. According to Biltekin et al. (2015) the Anatolian
423 refugium emerged after the retreat of the Paratethys Sea in the Pliocene and increasing
424 monsoon influence (increased summer rainfall) over the north-eastern Mediterranean region
425 (the latter accounting for the much higher summer precipitation in the Euxinian-Hyrcanian
426 than in the Mediterranean region). The Mediterranean climate type in Europe appeared first
427 during the late Pliocene and early Pleistocene (ca. 3.2–2.3 Ma; Suc, 1984) coinciding with
428 first large-scale north hemispheric glaciation in the North Atlantic (Denk et al., 2011).

430 **4.4 Detection of Miocene global climatic changes in the terrestrial fossil record**

431 High-resolution benthic stable isotopic data provide a detailed chronology of (global) climatic
432 changes across the Miocene Climatic Optimum (MCO), the middle Miocene Climatic
433 transition (MMCT), and the subsequent more pronounced cooling (Holbourn et al., 2014).
434 The terrestrial record usually does not provide the same temporal resolution but allows
435 focussing on regional patterns. The transition from MCO to MMCT has previously been
436 documented in high-resolution palynological analyses. For example, Jiménez-Moreno et al.
437 (2005) investigated a core from the Pannonian Basin and observed a decline of megathermic
438 taxa at the transition MCO to MMCT. Also Ivanov & Worobiec (2017) reported a decrease of

441 thermophile taxa for the transition for Bulgaria and Poland. In southwestern Anatolia, Kayseri
442 et al. (2014) investigated three localities in the Muğla-Ören area south of the Yatağan Basin,
443 which are dated by vertebrate fossils as early and late MN5 and thus correspond to the MCO.
444 These authors report a few warmth-loving elements (palms, *Avicennia*) that are missing in the
445 younger strata of the Yatağan Basin. This could be due to the deltaic setting of these floras as
446 opposed to the intramontane setting of the Yatağan Basin floras. In general, the floras of the
447 Muğla-Ören area are very similar to the floras of the Yatağan Basin (Bouchal. et al., 2017).
448 However, a striking difference with the MN6 and MN7+8 assemblages of the Yatağan Basin
449 is the almost entire absence of herbaceous taxa (non-arboreal pollen) in the MN5 assemblages
450 of Ören (see figs 7–9 in Kayseri et al. 2014). This may indicate the presence of more closed
451 forest vegetation of the laurisilva type. The extant laurisilva or laurel forest is a type of
452 subtropical forest found in areas with high humidity and relatively stable, mild temperatures.
453 The assemblages of the Yatağan Basin, show fluctuating arboreal to non-arboreal pollen
454 (AP:NAP) ratios with a peak of NAP in the transition zone MN6 to MN7+8 (pollen zone PZ
455 2–3). This peak could possibly correspond to a sharp cooling detected in the benthic stable
456 isotopic data at 13.9–13.8 Ma (Holbourn et al., 2014). In the European mammal stratigraphy
457 (Neubauer et al., 2015) the boundary MN6 to MN7+8 is at 13.9 Ma. Above PZ 2–3, the
458 radiometrically dated Yeni Eskihisar pollen assemblage clearly belongs to MN7+8. Here, **and**
459 **in the nearby locality Catakbağyaka** woody taxa (**including some warmth-loving taxa**) are
460 again more prominent. Thus, although the correlation of pollen zone 2–3 with the cooling
461 event at 13.9–13.8 Ma is highly speculative, it is clear that the MCO in southwestern Anatolia
462 was characterized by laurisilva vegetation with little contribution of herbaceous taxa. During
463 the MMCT the main woody taxa did not change much, but herbaceous taxa played a much
464 greater role. This indicates higher structural complexity of the vegetation. The presence of
465 early hominids in western Anatolia during this time might be connected to this more complex
466 vegetation. It is unclear at present, whether these changes were accompanied by changes in

470 concentrations of atmospheric CO₂. The compilation of reconstructed CO₂ values across the
471 Cenozoic from hundreds of proxy data (Beerling & Royer, 2011) shows that there is no
472 agreement between different proxies for the MCO and the subsequent middle Miocene
473 climate cooling. Phytoplankton stable isotopic data suggest nearly stable CO₂ concentrations
474 (MCO, 227–327 ppm, MMCT, 265–300 ppm; [see table S 1 of Beerling & Royer, 2011](#)). In
475 contrast, stomata densities from fossil leaves suggest a pronounced decline of CO₂ across this
476 interval.

Johannes Bouchal 28.8.18 14:01

Gelöscht: , table S1

477 478 **5. Conclusion**

479 Here we used three proxies to infer climate, palaeoenvironments and biogeographic affinities
480 of three middle Miocene floras of southwestern Anatolia. We showed that the palaeobotanical
481 record resolves transitions from the warm MCO (16.8–14.7 Ma) into the MMCT (14.7–13.9
482 Ma), and a more pronounced cooling at 13.9–13.8 Ma, mainly expressed in the changing and
483 fluctuating ratios between AP and NAP taxa. Using threshold percentages for main tree taxa,
484 we further show that although NAP values significantly increased during the MMCT, AP taxa
485 remained relatively abundant, signifying the coexistence of forested and open landscapes
486 during this transition. In addition, the biogeographic analysis indicates mainly northern
487 hemispheric biogeographic affinities of the middle Miocene flora of southwestern Anatolia
488 and thus invalidates previous comparisons with tropical environments. Tropical climate
489 conditions are also rejected by the Köppen signatures of the investigated floras and by the
490 CLAMP analysis. Finally, the CLAMP data readily distinguish between strongly seasonal Cs
491 and Cw and fully humid Cf climate types. More combined macrofossil and microfossil studies
492 are needed for the Neogene of Turkey in order to establish a robust framework of terrestrial
493 climate evolution in this important region.

494
495

497 **Author contribution**

498 JMB and TD designed the study. TD wrote the first draft of the manuscript. TG made the
499 CLAMP analysis, JMB made the Köppen signature analysis. All authors discussed the data
500 and contributed to the final version of the manuscript.

Supplementary Material.

S1: A. Number of fossil-taxa (macrofossils and microfossils) from four middle Miocene localities (including one macrofossil horizon and four pollen zones - PZ) in the Yatağan Basin.

B. All fossil-taxa recorded from four Yatağan Basin floras (14.8–13.2 Ma; MN6 into MN7–8).

S2: Köppen-Geiger climate type signatures of all genera represented in micro and macrofloras of the Yatağan Basin.

S3: Coding of leaf physiognomic characters for morphotypes from three macrofloras. Output pdf files from online CLAMP analysis (<http://clamp.ibcas.ac.cn>).

S4: Heat maps showing precise representation of different Köppen-Geiger climate types for all fossil assemblages.

S5: Köppen signature diagrams excluding cosmopolitan and gymnospermous taxa.

S6: Arboreal to non-arboreal pollen ratios for three sections, of the Yatağan Basin.

S7: Modern climate stations comparable to the middle Miocene climate of the Yatağan Basin, southwestern Anatolia. Climate data from CLIMATE-DATA.ORG (<https://sv.climate-data.org/info/sources/>) and Ustaoglu (2012). Selected Walter-Lieth climate diagrams illustrate qualitative difference between Euxinian-Hyrcanian and Japanese (Honshu) *Cf* climates.

Table 3

Description of Köppen-Geiger climate symbols and defining criteria			
1st	2nd	3rd	Description and criteria
A			equatorial / tropical ($T_{\text{cold}} \geq 18^\circ\text{C}$)
	f		rainforest, fully humid ($P_{\text{dry}} < 60\text{mm}$)
	m		monsoonal (not Af & $P_{\text{wet}} \geq 100\text{-MAP}/25$)
	s		savannah with dry summer ($P_{\text{dry}} < 60\text{mm}$)
	w		savannah with dry winter ($P_{\text{dry}} < 60\text{mm}$)
B			arid ($\text{MAP} < 10 \times P_{\text{month}}$)
	W		desert ($\text{MAP} < 5 \times P_{\text{month}}$)
	S		steppe ($\text{MAP} \geq 5 \times P_{\text{month}}$)
		h	hot arid ($\text{MAT} \geq 18^\circ\text{C}$)
		k	cold arid ($\text{MAT} < 18^\circ\text{C}$)
C			warm temperate/temperate ($T_{\text{hot}} > 10^\circ\text{C}$ & $0^\circ\text{C} < T_{\text{cold}} < 18^\circ\text{C}$)
D			snow / cold ($T_{\text{hot}} > 10^\circ\text{C}$ & $T_{\text{cold}} \leq 0^\circ\text{C}$)
		s	summer dry ($P_{\text{dry}} < 40$ & $P_{\text{dry}} < P_{\text{wet}}/3$)
		w	winter dry ($P_{\text{dry}} < P_{\text{wet}}/10$)
		f	fully humid / without a dry season (not s or w)
		a	hot summer ($T_{\text{hot}} \geq 22^\circ\text{C}$)
		b	warm summer (not a & $1 \leq T_{\text{hot}} < 22^\circ\text{C}$)
		c	cool / cold summer (not a or b & $T_{\text{hot}} < 10^\circ\text{C}$)
		d	extremely continental / very cold winter (not a or b & $T_{\text{cold}} < -38^\circ\text{C}$)
E			polar ($T_{\text{hot}} < 10^\circ\text{C}$)
	T		polar tundra ($T_{\text{hot}} \leq 10^\circ\text{C}$)

Table 3 Description of Köppen-Geiger climate symbols and defining criteria (Kottek et al., 2006; Peel et al. 2007). MAP = mean annual precipitation, MAT = mean annual temperature, T_{hot} = temperature of the hottest month, T_{cold} = temperature of the coldest month, $T_{\text{mon}10}$ = number of months where the temperature is above 10°C , P_{dry} = precipitation of the driest month, P_{sdrv} = precipitation of the driest month in summer, P_{wdry} = precipitation of the driest month in winter, P_{swet} = precipitation of the wettest month in summer, P_{wwet} = precipitation of the wettest month in winter, $P_{\text{threshold}}$ = varies according to the following rules (if 70% of MAP occurs in winter then $P_{\text{threshold}} = 2 \times \text{MAT}$, if 70% of MAP occurs in summer then $P_{\text{threshold}} = 2 \times \text{MAT} + 28^\circ$, otherwise $P_{\text{threshold}} = 2 \times \text{MAT} + 14$). Summer (winter) is defined as the warmer (cooler) six months period of ONDJFM and AMJJAS.
