15

16 **Abstract**

17 The middle Miocene climate transition (MMCT) was a phase of global cooling possibly
18 linked to decreasing levels of atmospheric CO₂. The MMCT coincided with the European
19 Mammal Faunal Zone MN6. From this time, important biogeographic links between Anatolia
20 and eastern Africa include the hominid *Kenyapithecus*. Vertebrate fossils suggested mixed
21 open and forested landscapes under (sub)tropical seasonal climates for Anatolia. Here, we
22 infer the palaeoclimate during the MMCT and the succeeding cooling phase for a middle
23 Miocene (14.8–13.2 Ma) of an intramontane basin in southwestern Anatolia using three
24 palaeobotanical proxies: (i) Köppen signatures based on the nearest-living-relative principle.
25 (ii) Leaf physiognomy analysed with the Climate Leaf Analysis Multivariate Program
26 (CLAMP). (iii) Genus-level biogeographic affinities of fossil floras with modern regions.
27 The three proxies reject tropical climates for the MMCT of southwestern Anatolia and instead
28 infer warm temperate C climates. Köppen signatures reject summer-dry Cs climates but
29 cannot discriminate between fully humid Cf and winter-dry Cw; CLAMP reconstructs Cf
30 climate based on the low X3.wet/X3.dry ratio. Additionally, we assess whether the
31 palaeobotanical record does resolve transitions from the warm Miocene Climatic Optimum
32 (MCO, 16.8–14.7 Ma) into the MMCT (14.7–13.9 Ma), and a more pronounced cooling at
33 13.9–13.8 Ma, as reconstructed from benthic stable isotope data. For southwestern Anatolia,
34 we find that arboreal taxa predominate in MCO floras (MN5), whereas in MMCT floras
35 (MN6) abundances of arboreal and non-arboreal elements strongly fluctuate indicating higher
36 structural complexity of the vegetation. Our data show a distinct pollen zone between MN6
37 and MN7+8 dominated by herbaceous taxa. The boundary MN6 and MN7+8, roughly
38 corresponding to a first abrupt cooling at 13.9–13.8 Ma, possibly might be associated with
39 this herb-rich pollen zone.

40

41 **Keywords:** Miocene; plant fossil; climate proxy; Köppen signatures; CLAMP; biogeography

42 **1 Introduction**

43 The middle Miocene (15.97–11.63 Ma, ICS-chart 2017/02, Cohen, 2013) is characterized by
44 a warm phase lasting until ca. 15 Ma that was followed by a gradual cooling and the
45 restoration of a major Antarctic ice sheet and first northern hemispheric glaciations (Holbourn
46 et al., 2014). It has been suggested that the final closure of the Mediterranean gateway
47 connecting the Mediterranean with the Indian Ocean and the resulting changes in ocean
48 circulation might have been one of the reasons for the final expansion of the East Antarctic
49 ice sheet around 14.8 Ma (Flower & Kennett, 1993). During the middle Miocene climate
50 transition (MMCT) at 14.7 to 13.8 Ma a drop of sea surface temperatures of 6–7°C occurred
51 (Shevenell et al., 2004). At the same time, different proxies to reconstruct atmospheric CO₂
52 levels for the Miocene Climatic Optimum (MCO), MMCT, and the succeeding more
53 pronounced cooling, do not concur (Beerling & Royer, 2011). Specifically, stable isotope data
54 from phytoplankton infer stable CO₂ levels for the Neogene, with minor fluctuations (MCO,
55 227–327 ppm, MMCT, 265–300 ppm; Beerling & Royer, 2011, table S1), while stomata
56 densities from fossil leaves suggest a pronounced drop of CO₂ after the MCO (Beerling &
57 Royer, 2011, table S1).

58 The European Mammal Faunal Zone MN6 (14.8–13.8 Ma; Neubauer et al., 2015) coincides
59 with the MMCT. From this period world-famous vertebrate faunas are known from western
60 Anatolia (e.g. Andrews & Tobien, 1977; Mayda et al., 2015) including the hominoids
61 *Griphopithecus alpani* in Çandır and Paşalar, and *Kenyapithecus kizili* in Paşalar (Stringer &
62 Andrews, 2011). Geraads et al. (2003) investigated the depositional environment and large
63 mammal fauna of Çandır close to Ankara and inferred open landscapes for this locality.
64 Bernor et al. (1979, p. 86) analysed community structure of Turkish and European middle
65 Miocene faunas and suggested that “faunas adapted to woodland conditions were present ...
66 at localities such as Paşalar and Yeni Eskişehir [MN7-8]” while the “Çandır fauna has a
67 community structure more suggestive of closed woodland conditions”. This interpretation is

68 the exact opposite of that by Geraads et al. (2003). Recent investigations using carnivore guild
69 structure suggest a “*mixed environment between tropical forest and open savannah*
70 *landscapes*” for Çandır and Paşalar (Mayda et al., 2015). Strömberg et al. (2007) investigated
71 phytoliths (plant silica bodies) from early to late Miocene deposits of Turkey and suggested
72 that open, grass-dominated habitats had become common in Turkey and adjacent areas by the
73 early Miocene (c. 20 Ma). In contrast, Kayseri-Özer (2017) using ‘integrated plant record’
74 (IPR) analysis (Kovar-Eder et al., 2008) suggested that various forest types covered most of
75 western and Central Anatolia during the middle Miocene (*broad-leaved evergreen* and *mixed*
76 *mesophytic forests* and ecotones between these forests).

77 Here we use a large data set from recently published macrofossils and pollen, spores and cysts
78 from a well-dated middle Miocene basin in western Anatolia to infer palaeoclimate and
79 palaeoenvironments using three palaeobotanical proxies: climate affinity of modern analogues
80 (‘nearest living relatives’; taxon-based approach), leaf physiognomy (a-taxonomic), and
81 biogeographic affiliation of plant communities (also taxon-based). The following research
82 questions are addressed: How do the three approaches resolve local climate conditions of
83 Anatolia during a phase of global cooling, ca. 15–13 million years ago? Do different proxies
84 agree on climate inference? Where do modern climates occur that correspond to middle
85 Miocene climates of western Anatolia? Can the palaeobotanical record resolve transitions
86 between MCO, MMCT, and the succeeding more pronounced cooling during the middle
87 Miocene?

88

89 **2 Material and methods**

90 **2.1 Geological setting**

91 The Yatağan Basin is a southeast trending graben (50 km long, 15 km wide) in the province
92 of Muğla, southwestern Turkey (Fig. 1). The Neogene basin fill is up to 600 m thick and
93 divided into the Eskihisar Formation (early to middle Miocene), the Yatağan Formation (late

94 Miocene to early Pliocene), and the Milet Formation (middle to late Pliocene; Alçiçek, 2010).
95 The Eskihisar Formation comprises the Turgut Member (reddened alluvial-fan deposits
96 followed by fluvial deposits and lignites) and the Sekköy Member (fossiliferous limnic
97 marls and limestones); all economically exploited lignite seams of the Yatağan Basin are
98 confined to the transition zone of these two members (Atalay, 1980; Becker-Platen, 1970).
99 For the present study, we investigated the palaeobotanical content (pollen and plant
100 macrofossils) of the upper Turgut and the Sekköy members exposed at the lignite mines of
101 Eskihisar, Salihpaşalar, and Tınaz (Fig. 1.2). The age of the investigated sediments is well
102 constrained by mammal fossils (Eskihisar lignite gallery locality, MN6, *Gomphotherium*
103 *angustidens* Cuvier 1817, *Percrocuta miocenica* Pavlov et Thenius 1965, Bouchal et al.,
104 2017; Yeni Eskihisar vertebrate locality, MN 7/8, The NOW Community, 2018), and by
105 radiometric dates from the upper Sekköy Member (13.2 Ma ± 0.35, Becker-Platen et al.,
106 1977). Hence, the investigated pollen zones (PZ) 1, 2, 2/3, and the Yeni Eskihisar pollen
107 assemblage represent the Neogene mammal zones MN6 and MN7+8, 14.8–13.2 Ma;
108 Neubauer et al., 2015). The layers from which most of the leaf fossils originate correspond to
109 PZ 2. A ~20 m section comprised of limestone and clayey limestone between PZ 2/3 and the
110 Yeni Eskihisar assemblage is barren of palynological content (Fig. 2).

111

112 **2.2 Plant material**

113 The investigated plant material comprises roughly 1800 macrofossils (mainly leaf fossils)
114 collected between 2010 and 2017. Macrofossils represent 77 taxa, of which five belong to
115 gymnosperms and 72 to angiosperms. Pollen, spores and cysts from five pollen zones (Fig. 2)
116 represent 182 taxa, of which one is a fungus, 9 are algae, 17 moss or fern allies spores, 15
117 gymnosperms, and 140 angiosperms (Supplementary Material S1; for taxonomic descriptions
118 of the plant taxa see Yavuz-Işık et al., 2011; Bouchal et al., 2016, 2017; Bouchal, in press;
119 Güner et al., 2017).

120

121 **2.3 Köppen signatures**

122 Fossil taxa that are resolved to genus or sectional level were represented by extant members
123 of the genera and sections as modern analogues. First, for accepted taxa (IPNI,
124 <http://www.ipni.org/index.html>; most recent regional floras and monographs) their
125 distribution ranges were determined. Then, 26 Köppen-Geiger climate types (see
126 Supplementary Material S2 for detailed explanation of Köppen-Geiger climate types, and
127 Kottek et al., 2006; Peel et al., 2007, Rubel et al., 2017; Global_1986-2010_KG_5m.kmz)
128 were mapped on modern distribution ranges using Google Earth to establish ‘Köppen
129 signatures’ (Denk et al. 2013) for each modern analogue. Representation of different climate
130 types was first scored for each species within a genus as present (1)/absent (0). To summarize
131 preferences for climate types of all modern analogues, we used an implicit weighting scheme
132 to discriminate between modern analogues that are highly decisive (climatically constrained)
133 vs. those that can be found in many climate zones. The sum of each modern species’ Köppen
134 signature is always one. For example, *Tilia chingiana* is present in two Köppen-Geiger
135 climate types, *Cfa* and *Cfb*, which count as 0.5 for each type, while *Tilia americana* is present
136 in ten Köppen-Geiger climate types (*As*, *Aw*, *Cfa*, *Cfb*, *Dfa*, *Dfb*, *Cwa*, *Cwb*, *BSk*, *BWh*), all
137 counting as 0.1. The Köppen signature of a genus or section, the modern analogue of a fossil
138 taxon, is the sum of its species’ Köppen signatures for each climate type divided by the total
139 number of scored species for this genus. By this, the percentage representation of each
140 Köppen-Geiger climate type was determined for a genus/ section. In case of *Tilia*, the
141 distribution ranges of 26 species resulted in a genus Köppen signature as follows: *Cfa*, 22.1%,
142 *Cfb*, 14.7%, *Cwa*, 19.9%, *Cwb*, 9.1%, *Dfb*, 5.7%, for the five most common climate types.
143 Fig. 3.1 shows all climate types realized in genus *Tilia*; Fig. 3.2 shows that the genus occurs
144 predominantly in *Cf* and *Cw* Köppen-Geiger climate types and that tropical and desert

145 climates are nearly absent (see Supplementary Material S3 for genus-level scoring of Köppen-
146 Geiger climate types for all plant taxa encountered in the Yatağan basin fossil assemblages).
147 For taxa that are resolved to family-level only, mainly pollen taxa of herbaceous and a few
148 woody angiosperm groups, the distributions of extant members of the family were combined
149 into a general family distribution range and the corresponding Köppen-Geiger climate types
150 determined.
151 Genus-level Köppen-Geiger signals were used to account for possible niche evolution within
152 lineages/ species groups of a genus. For example, modern species of *Quercus* section *Ilex* are
153 typical members of sclerophyllous, evergreen Mediterranean forest and shrubland vegetation
154 thriving under a *Cs* (summer-dry warm temperate) climate in western Eurasia and along the
155 western parts of the southern foothills of the Himalayas, but also occur in humid, mesophytic
156 forests from Afghanistan to East Asia (*Cf* and *Cw* climates). To account for this climate niche
157 variability, all species of sect. *Ilex* were scored for the general Köppen signature of sect. *Ilex*.
158 Hence, the entire section was used as modern analogue, the nearest living relative (NLR), for
159 several fossil species of *Quercus* sect. *Ilex*.

160

161 **2.4 CLAMP**

162 We inferred quantitative palaeoclimate parameters for the three Yatağan Basin floras using
163 the Climate Leaf Analysis Multivariate Program (CLAMP) (Yang et al., 2011). CLAMP
164 makes use of the relationship between leaf physiognomy and climate and, hence, is a non-
165 taxonomic approach to palaeoclimate inference (Spicer, 2008). Modern and fossil leaf
166 physiognomic data are positioned in multidimensional physiognomic space using high
167 resolution gridded climate data and canonical correspondance analysis. For details on the
168 methodology see the CLAMP website (<http://clamp.ibcas.ac.cn>).
169 For the present study, 36 different leaf characters were scored for 61, 63, and 14
170 dicotyledonous leaf morphotypes from three localities, Tınaz, Eskihisar, and Salihpaşalar (see

171 Supplementary Material S4 for scoring of morphotypes), following the CLAMP protocols
172 (<http://clamp.ibcas.ac.cn>). At genus level, the floras of the Yatağan Basin show highest
173 similarity with Eurasian extant woody angiosperms (Table 1), thus the PhysgAsia1
174 Calibration files dataset of CLAMP was used to position the fossil data.

175

176 *2.5 Genus level biogeographic affinities*

177 For all fossil taxa determined to genus level, the present distribution was tabulated indicating
178 presence/absence of a genus in western Eurasia, East Asia, eastern North America, western
179 North America, and Africa (Table 1).

180

181 **3 Results**

182 **3.1 Climate inference from Köppen signatures** (Fig. 5, Supplementary Materials S5, S6)

183 For the fossil plant assemblages warm temperate to temperate *C* and *D* climates accounted for
184 almost 80% of the realized Köppen-Geiger climate types of all taxa in a fossil plant
185 assemblage (using genus-level NLR). The sum of *C_f*, *D_f*, *C_w* and *D_w* climates amounted to
186 60–70% in all assemblages (highest scores in macrofossil assemblages).

187 Overall, the best represented Köppen-Geiger climate types when using genus-level NLR were
188 *C_{fa}* (warm temperate, fully humid, hot summer), followed by *C_{fb}* (warm temperate, fully
189 humid, warm summer), *C_{wa}* (warm temperate, winter-dry, hot summer), and *C_{wb}* (warm
190 temperate, winter-dry, warm summer). Summer-dry *C_s* climates were represented by 9–13%
191 and arid (generally dry) *B* climates by 6–11% (Supplementary Materials S2, S5). Tropical
192 (equatorial) climates (*A*) are represented by 9–11% in older assemblages, and 7–8% in the
193 two youngest assemblages (PZ 2/3 and Yeni Eskihisar). Of 1555 modern species used to
194 inform the Köppen signatures of the NLRs for the fossil taxa, 119 show (marginal???) range
195 extensions into *A_f* climate, 168 into *A_m* (heavy monsoon), 85 into *A_s*, and 295 into *A_w*
196 (Supplementary Material S3). Taxa extending in tropical climates are mainly species of

197 *Celtis*, *Smilax*, and *Viburnum*, *Quercus* sections *Quercus* and *Lobatae*, Juglandaceae
198 subfamily Engelhardioideae, Oleaceae, and Sapotaceae. Exclusion of Köppen-Geiger climate
199 signals extracted from cosmopolitan and/or gymnospermous taxa did not change the general
200 trends (Supplementary Material S6).

201

202 **3.2 CLAMP**

203 Sixty-three morphotypes were scored for Eskihisar (Fig. 6; see Supplementary Material S4 for
204 score sheets and other reconstructed climate parameters). Inferred values for mean annual
205 temperature (MAT) were (11.2–) 12.6 (–14) °C, for coldest month mean temperature
206 (CMMT) (0.3–) 2.3 (–4.4) °C, and for the three wettest months (X3.wet) (410–) 666 (–936)
207 mm and for the three driest months (X3.dry) (148–) 204 (–262) mm. The ratio X3.wet/X3.dry
208 was between 2.9 and 3.6. For Tinaz, the reconstructed MAT was (12.3–) 13.8 (–15.2) °C,
209 CMMT (1.5–) 3.6 (–5.6) °C, X3.wet (420–) 700 (–980) mm, and X3.dry (146–) 205 (–260)
210 mm. The ratio X3.wet/X3.dry was between 2.9 and 3.8. Values for Salihpaşalar are not
211 considered here as they are based on a too small set of morphotypes (see Supplementary
212 Material S4).

213

214 **3.3 Genus level biogeography**

215 The genus-level biogeographic analysis of the four Yatağan Basin floras ranging in age from
216 14.8 to 13.2 Ma (MN6 into MN+/8; Table 1) shows that closest biogeographic relationships
217 are with the modern East Asian flora (54 of 59 taxa shared with East Asia), 48 and 44 genera
218 are shared with the modern western Eurasian and eastern North American floras, respectively.
219 Among modern tropical floras, closest relationships are with South America (21), followed by
220 Africa (16) and northern/ north-eastern Australia (13). Most taxa extending to tropical regions
221 are cosmopolitan (e.g. *Euphorbia*, *Drosera*, *Phragmites*), hence, of little discriminative
222 power. This is also true for higher taxa such as Polygalaceae and Valerianoideae. The fossil

223 species *Smilax mihovanensis* belongs to a subtropical-tropical clade of extant species (Denk
224 et al., 2015) and is the only member of this group in Eurasia; it has its last occurrence in the
225 middle Miocene floras of the Yatağan Basin. Overall, the dominating biogeographic signal is
226 a northern hemispheric one.

227

228 **3.4 Changes in ratios arboreal to non-arboreal pollen**

229 Ratios of arboreal pollen (AP) to non-arboreal pollen (NAP) change considerably among and
230 within pollen zones of the Yatağan Basin assemblages (Table 2, Supplementary Material S7).
231 Pollen zone 1 (main lignite seam) consistently has high percentages of AP (94–70%). In
232 contrast, AP percentage values fluctuate throughout pollen zone 2, with values from 89 to 29.
233 Pollen zone 2-3, only covered in the Tınaz section, records AP percentages of 50 to 19.
234 Above, the MN7+8 assemblage of Yeni Eskihsar shows again a higher proportion of arboreal
235 taxa (67%).

236

237 **4 Discussion**

238 **4.1 Climate inference using Köppen signatures and CLAMP**

239 Using Köppen signatures, we made a semi-quantitative reconstruction of the palaeoclimate of
240 the Yatağan Basin during the middle Miocene. All Köppen signatures used here rely on the
241 nearest-living-relative principle (Denk et al., 2013). Such approaches are prone to error
242 because niche evolution may have occurred in lineages, the morphologically nearest living
243 relatives (NLRs), a species or group of morphologically similar species, of fossil taxa may
244 have different niches, and the shift is difficult to quantify (Ackerly, 2004; Grimm & Potts,
245 2016; Denk et al., 2017). Hence, we opted against applying quantitative NLR methods and
246 determined Köppen signatures for fossil taxa using information from all extant species of a
247 genus used as NLR to avoid bias from undetected niche shifts.

248 It is important to keep climatic niche shift in mind when using NLR based approaches to
249 palaeoclimate inference and interpreting their results (cf. Grimm & Potts, 2016; Denk et al.,
250 2017). In our dataset of 1555 modern species, 295 also occur in tropical *Aw* climates. Most of
251 them belong to clades (monophyletic sections, genera, families) that occur in a wide range of
252 climate types (e.g. *Amaranthaceae*, *Celtis*, white and red oaks). Others, such as *Engelhardia*
253 are usually interpreted as tropical-subtropical evergreen element (Kvaček, 2007) based on the
254 distribution range of the extant genera of the comprising subfamily, the Engelhardioideae.
255 However, ‘*Engelhardia*’ of the western Eurasian Cenozoic belongs to its own (extinct)
256 section or genus *Palaeocarya* (Kvaček, 2007) with a stratigraphic range from Eocene to
257 Pliocene. Pollen, foliage, and reproductive structures of fossil material clearly belong to
258 subfamily Engelhardioideae but cannot be assigned to just a single modern genus *Engelhardia*
259 (tropical Southeast Asia). Instead the fossil-taxon is a mosaic taxon having characteristics of
260 both American and Asian members of the subfamily. Kvaček (2007) noted that the fossil
261 genus/subgenus flourished in subtropical climates during the Eocene but in distinctly
262 temperate climates with coldest month mean temperatures close to the freezing point in the
263 Neogene, in stark contrast to the surviving four, likely relict genera of the Engelhardioideae.
264 Hence, this extinct lineage of Engelhardioideae is not well represented by a single or the
265 combination of all extant genera and their constituent species. Similarly, representatives of
266 *Smilax havanensis* and allied species are part of a New World clade with most species
267 occurring in tropical climates. However, the single Old World member of the clade, the fossil
268 species *S. miohavanensis*, is known from early to middle Miocene strata of Anatolia and
269 Central Europe (Denk et al., 2015). This fossil species formed part of plant assemblages that
270 rule out tropical climates. In this case, inferring palaeoclimate from extant distribution data
271 only inevitably will produce noise to the climatic signal.
272 Overall, the most common Köppen-Geiger climate types of NLR taxa of the Yatağan floras
273 were warm temperate *C* types, and among *C* types fully humid *Cf* climates were better

274 represented than more seasonal C_w and C_s types (Fig. 5; Supplementary Material S5). C_s
275 types played only a minor role; however, there was no clear preference of C_f over C_w
276 climates in the representation of Köppen-Geiger climate types. Removing azonal taxa, or taxa
277 commonly associated with higher elevations (conifers) did not affect the general signal.
278 In contrast, CLAMP is not based on NLR and hence not potentially biased by taxonomic
279 error. Its combination with the Köppen signature analysis provides a powerful tool for climate
280 inference and to discern between seasonal C_w (winter dry) and C_s (summer dry) and fully
281 humid C_f climates can be made. Specifically, the ratio of the wettest and the driest month
282 clearly distinguishes strongly seasonal summer rain (monsoon) climates (C_w ; precipitation
283 wettest month $> 10x$ precipitation driest month, [$P_{\text{wdry/sdry}} < P_{\text{wet/wwet}}/10$]; Peel et al., 2007)
284 from weakly seasonal, fully humid climates (C_f ; precipitation wettest month $\ll 10x$
285 precipitation driest month). Precipitation values for X3.wet and X3.dry inferred by CLAMP,
286 and the ratio between these ranges being between 2.9 and 3.8 thus largely rules out a C_w
287 climate (X3.wet and X3.dry are closely correlated to $P_{\text{dry/wet}}$). In conjunction with the Köppen
288 signature results ruling out summer-dry conditions, the CLAMP precipitation and temperature
289 estimates point towards cold subtropical to mild temperate C_{fa} climates at the margin to fully
290 temperate C_{fb} climates.

291

292 **4.2 Comparison to palaeoclimate and palaeoenvironment inferences from other proxies**

293 A further refinement of previous climate and vegetation inferences can be made regarding the
294 distinction between tropical ($T_{\text{min}} \equiv \text{CMMT} \geq 18^\circ \text{C}$), subtropical (X months with $T \geq 10^\circ \text{C}$;
295 $\sim \text{MAT}$ of xxx–xxx $^\circ \text{C}$, and CMMT of xxx–xxx $^\circ \text{C}$) and temperate climates. CLAMP
296 consistently resolves $\text{MAT} < 18^\circ \text{C}$ and $\text{CMMT} < 6^\circ \text{C}$ for the localities Eskihisar and Tınaz,
297 and this agrees with the results from Köppen signatures and a previous qualitative assessment
298 of palaeoenvironments in the Yatağan Basin (Güner et al., 2017). Both these results, rejecting
299 strongly seasonal C_w climates, summer dry C_s , and tropical A climates (at least for non-

300 coastal areas) for the middle Miocene of western Anatolia, have implications for the
301 reconstruction of palaeoenvironments of famous vertebrate localities in Anatolia that are
302 assigned to MN6. The $\delta^{13}\text{C}$ composition from fossil tooth enamel at Paşalar, western
303 Anatolia, MN6, indicates that animals were feeding on C_3 vegetation (Quade et al., 1995).
304 The palaeoenvironment for this locality was determined as closer to Indian subtropical
305 forests, with seasonal summer rainfalls (i.e. warm *Cwa* climates), semi-deciduous forest and
306 dense ground vegetation (Stringer & Andrews, 2011; Mayda et al., 2015). Using carnivore
307 guild structures Morlo et al. (2010) inferred open (Serengeti type, *Aw* climate) landscapes for
308 the Central Anatolian MN6 vertebrate locality Çandır. Also, the NOW database
309 (<http://www.helsinki.fi/science/now/>; The NOW Community, 2018) refers to Çandır as more
310 open (“woodland biome”, “open vegetation structure”, “grassland with mosaic of forests”)
311 and to Paşalar as more forested landscapes (“subtropical”, “closed vegetation structure”,
312 “semi-deciduous forests”). Bernor et al. (1979) using community structure of vertebrate
313 faunas inferred densely wooded environments for Çandır. In a later study based on a
314 taxonomic revision of carnivores, Mayda et al. (2015) proposed a mixed environment
315 between tropical forests and open savannah landscapes for Çandır. It is important to note that
316 these carnivore guild structure studies used only two modern calibration faunas to estimate
317 palaeoenvironments, one tropical rainforest fauna in Guyana, and one savannah (tropical)
318 fauna in the Serengeti (Morlo et al., 2010). Thus, using this proxy, only two environments can
319 be reconstructed, tropical savannah or rainforest.

320 Our plant-proxy based climate reconstruction unambiguously rejects a tropical climate for the
321 middle Miocene Yatağan Basin and major biogeographic patterns strongly suggest northern
322 hemispheric affinities. Similar environmental conditions as reconstructed in our study have
323 been inferred for most of western Anatolia during the late early and middle Miocene
324 (Kayseri-Özer, 2017). Most proxies currently used to infer climate and vegetation in western
325 Anatolia during the middle Miocene (carnivore guild structures, vertebrate community

326 structure, plant functional types, plant macrofossils, pollen and spores; Mayda et al., 2015,
327 2016; Kayseri-Özer, 2017; Güner et al., 2017; Bouchal et al. 2016, 2017; Bouchal, 2018)
328 clearly infer forested vegetation with varying contributions of open vegetation. In contrast,
329 Strömberg et al. (2007) found that “*all Miocene phytolith assemblages point to relatively open*
330 *vegetation, such as savanna or open woodland dominated by open-habitat grasses, or a*
331 *mixture of grassland and wooded areas*”. This result may be strongly biased (see Jokela,
332 2015, p. 44) and increased diversity of grass types in the phytolith record may not actually
333 indicate the presence of widespread open, grass-dominated landscapes.

334

335 **4.3 Modern climate analogues**

336 The inferred climate for the middle Miocene Yatağan Basin plant assemblages is
337 characterized by MAT 11–15 °C, coldest month mean temperature (CMMT) 0–6 °C, MAP
338 ca. 1000–2000 mm, and ratios of X3.wet/X3.dry 2.9–3.8. A non-exhaustive search for climate
339 stations with this combination of climate parameters (Supplementary Material S8) identified a
340 single closest match, Pacific central Honshu of Japan. X3.wet/X3.dry ratios and MAT are
341 similar to the upper limits of the ranges reconstructed for the middle Miocene Yatağan Basin.
342 East Asian *Cf* climates are generally characterized by distinct summer rain maxima. The
343 modern vegetation of Japan is home to many plant taxa that are currently absent from western
344 Eurasia but were abundant in Neogene plant assemblages of western Eurasia (e.g.
345 *Cephalotaxus*, *Cryptomeria*, *Torreya*, *Alangium*, *Camellia*, *Castanopsis*, *Cercidiphyllum*,
346 *Daphniphyllum*, *Eurya*, *Fatsia*; Mai, 1995; Miyawaki, 1984; see also Milne, 2004). These
347 taxa require warm and humid equable climates.
348 A further close match is the area from northern Turkey via Georgia to northern Iran, the
349 Euxinian-Hyrcanian region (Supplementary Material S8). Climates at the transition between
350 *Csa* and *Cfa/b* of the region north of Istanbul have up to 1166 mm MAP (Ustaoglu, 2012) and
351 other climate parameters in this area match the Miocene climate of southwestern Turkey

352 inferred by CLAMP. Towards the humid north-eastern part of Turkey, X3.wet/X3.dry ratios
353 are lower (2.4 for Rize, Hopa and Poti and Kobuleti in adjacent western Georgia). Further to
354 the east, south of the Caspian Sea, Rasht and Kiashahr have *Cfa* and borderline *Csa* to *Cfa*
355 climates with slightly more pronounced seasonality than the reconstructed climate for the
356 Miocene of southwestern Turkey (X3.wet/X3.dry ratios 4.4 and 4.2). In contrast,
357 X3.wet/X3.dry ratios in modern Mediterranean western and southwestern Turkey amount to
358 25 (Izmir) and 21.8 (Muğla, Yatağan Basin). It is noteworthy that modern *Cf* climates of the
359 Euxinian-Hyrcanian region differ markedly from those of the Pacific part of Honshu by their
360 summer minima in rainfall (Supplementary Material S8). This feature indicates a (weak)
361 Mediterranean influence in this region. According to Biltekin et al. (2015) the Anatolian
362 refugium emerged after the retreat of the Paratethys Sea in the Pliocene and increasing
363 monsoon influence (increased summer rainfall???) over the north-eastern Mediterranean
364 region (the latter accounting for the much higher summer precipitation in the Euxinian-
365 Hyrcanian than in the Mediterranean region). The Mediterranean climate type in Europe
366 appeared first during the late Pliocene and early Pleistocene (ca. 3.2–2.3 Ma; Suc, 1984)
367 coinciding with first large-scale north hemispheric glaciation in the North Atlantic (Denk et
368 al., 2011).

369

370 **4.4 Detection of Miocene global climatic changes in the terrestrial fossil record**

371 High-resolution benthic stable isotopic data provide a detailed chronology of (global) climatic
372 changes across the Miocene Climatic Optimum (MCO), the middle Miocene Climatic
373 transition (MMCT), and the subsequent more pronounced cooling (Holbourn et al., 2014).
374 The terrestrial record usually does not provide the same temporal resolution but allows
375 focussing on regional patterns. The transition from MCO to MMCT has previously been
376 documented in high-resolution palynological analyses. For example, Jiménez-Moreno et al.
377 (2005) investigated a core from the Pannonian Basin and observed a decline of megathermic

378 taxa at the transition MCO to MMCT. Also Ivanov & Worobiec (2017) reported a decrease of
379 thermophile taxa for the transition for Bulgaria and Poland. In southwestern Anatolia, Kayseri
380 et al. (2014) investigated three localities in the Muğla-Ören area south of the Yatağan Basin,
381 which are dated by vertebrate fossils as early and late MN5 and thus correspond to the MCO.
382 These authors report a few warmth-loving elements (palms, *Avicennia*) that are missing in the
383 younger strata of the Yatağan Basin. This could be due to the deltaic setting of these floras as
384 opposed to the intramontane setting of the Yatağan Basin floras. In general, the floras of the
385 Muğla-Ören area are very similar to the floras of the Yatağan Basin (Bouchal. et al., 2017).
386 However, a striking difference with the MN6 and MN7+8 assemblages of the Yatağan Basin
387 is the almost entire absence of herbaceous taxa (non-arboreal pollen) in the MN5 assemblages
388 of Ören (Table 2). This may indicate the presence of more closed forest vegetation of the
389 laurisilva type. The assemblages of the Yatağan Basin, show fluctuating arboreal to non-
390 arboreal pollen (AP:NAP) ratios with a peak of NAP in the transition zone MN6 to MN7+8
391 (pollen zone PZ 2–3). This peak could possibly correspond to a sharp cooling detected in the
392 benthic stable isotopic data at 13.9–13.8 Ma (Holbourn et al., 2014). In the European mammal
393 stratigraphy (Neubauer et al., 2015) the boundary MN6 to MN7+8 is at 13.9 Ma. Above PZ
394 2–3, the radiometrically dated Yeni Eskihisar pollen assemblage clearly belongs to MN7+8.
395 Here, woody taxa are again more prominent. Thus, although the correlation of pollen zone 2–
396 3 with the cooling event at 13.9–13.8 Ma is highly speculative, it is clear that the MCO in
397 southwestern Anatolia was characterized by laurisilva vegetation with little contribution of
398 herbaceous taxa. During the MMCT the main woody taxa did not change much, but
399 herbaceous taxa played a much greater role. This indicates higher structural complexity of the
400 vegetation. The presence of early hominids in western Anatolia during this time might be
401 connected to this more complex vegetation. It is unclear at present, whether these changes
402 were accompanied by changes in concentrations of atmospheric CO₂. The compilation of
403 reconstructed CO₂ values across the Cenozoic from hundreds of proxy data (Beerling &

404 Royer, 2011) shows that there is no agreement between different proxies for the MCO and the
405 subsequent middle Miocene climate cooling. Phytoplankton stable isotopic data suggest
406 nearly stable CO₂ concentrations (MCO, 227–327 ppm, MMCT, 265–300 ppm; Beerling &
407 Royer, 2011, table S1). In contrast, stomata densities from fossil leaves suggest a pronounced
408 decline of CO₂ across this interval.

409

410 **Author contribution**

411 JMB and TD designed the study. TD wrote the first draft of the manuscript. TG made the
412 CLAMP analysis, JMB made the Köppen signature analysis. All authors discussed the data
413 and contributed to the final version of the manuscript.

414
