18 **Abstract**

19 The Ancient Silk Road played a crucial role in cultural exchange and commercial
20 trade between western and eastern Eurasia during the historical period. However, the
21 exchanges were interrupted in the early 16th century AD, in the Ming dynasty. Three
22 causes of the **decline** of the ancient Silk Road have been suggested: (1) the thriving of the
23 sea trade route following major geographical discoveries in the Ming dynasty; (2)
24 frequent incursions by the **Oirat** and Turpan kingdoms, or fighting in border areas; and (3)
25 climate change. In this study, new evidence from a sedimentary site in Dunhuang oasis,
26 together with analysis of historical archives, indicate that neither the sea trade route nor
27 the frontier wars were the tenable explanation for the decline of the ancient Silk Road.
28 However, the desertification event that caused by climate change might have played a
29 crucial role in the abrupt decrease of trade exchange on the ancient Silk Road around
30 1450 AD. XSW site in this study indicated that, extreme droughts and desertification
31 events occurred in the Dunhuang area post ~1450 AD and persisted for decades at least.
32 The desertification reduced the accessibility of the ancient Silk Road in this area, which
33 was responsible for a steep fall in the volume of trade as well as political chaos and mass

34 **migrations.** The final closure of the Jiayuguan Pass in 1539 AD and the abandonment of
35 Dunhuang city further accelerated the decline of the ancient Silk Road.

36 **Keywords:** Dunhuang; Ancient Silk Road; climate change; desertification; Ming dynasty

37

38 1. Introduction

39 The Ancient Silk Road was the most important link between nations in Eurasia from
40 the 2nd century BC to the 16th century AD, and thus it indirectly shaped the politics,
41 cultures and economies of populations across the Eurasian continent. The route not only
42 linked commercial trade between the East and West but it also facilitated the spread of
43 religion, technology and even diseases such as the plague (Jones et al., 2011; Chen et al.,
44 2015; Schmid et al., 2015; Frankopan, 2015; An et al., 2017; Dong et al., 2017a; **Hao et**
45 **al., 2019**; Afzaal, 2020). As a routeway, the Ancient Silk Road reached a peak in the Tang
46 dynasty (618-907 AD), but the grandeur came to an end in the 16th century AD with the
47 closure of the Jiayuguan Pass by the central government in China and the abandonment of
48 Dunhuang city in the Ming dynasty (1368-1644 AD). This event was an important marker
49 in terms of the depression of cultural exchange and trade between East and West, and the
50 decline of the Ancient Silk Road as an historically important routeway.

51 The Chinese section of the Ancient Silk Road passes through one of the driest regions
52 on Earth and the logistical operation of the road depended directly on the oases that
53 developed along the foot of the high mountain ranges (the Qilian, Kunlun and Tianshan),
54 mainly as a result of precipitation supplied as streamflow from the highlands. Cities and
55 towns emerged and developed in association with oases, such as Jiayuguan, Dunhuang,
56 Hami and Ruoqiang, which functioned as logistical stations for trade between East and
57 West along the Ancient Silk Road. The Jiayuguan Pass is at the western end of the Great
58 Wall in the Ming dynasty. Located at the narrowest point of the Hexi Corridor, the
59 Jiayuguan Pass was also a critical location on the primary routeway between the western
60 Gobi Desert and the domains of the Ming dynasty. Dunhuang commandery was 300 km
61 from the Jiayuguan Pass and the traffic hub which constituted the historic junction of
62 several routes along the Ancient Silk Road in Central Asia (Huang, 2008). It passed to the
63 control of the central government in 1372 AD, in the early Ming dynasty. **The Ming**
64 **governor established seven garrisons in the Jiayuguan-Dunhuang area and transferred the**
65 **leadership to Mongolia which governed the seven garrisons in order to consolidate the**
66 **frontier territory (Chen, 2000).**

67 Various hypotheses have been proposed to explain the **decline** of the Ancient Silk
68 Road during the later Ming Dynasty. For example, frequent wars in the Dunhuang area
69 have been suggested (Chen, 2011; Li and Zheng, 2013). In the Middle and Late Ming
70 dynasty, national power declined due to political corruption and financial stresses, but the
71 border nations such as **Oirat** and Turpan continued to expand (**Zhang, 1974**).
72 Agri-nomadic wars (conflict between agriculturalists and nomads) and conflict between
73 the seven garrisons and invasions by nomadic tribes in the Hexi Corridor were frequent.

74 The border policy of the administration weakened and there was a gradual isolation of the
75 governance (Research Institute of History and Language of the Central Academy in
76 Taiwan, 1962a, Zhang, 1974), and as consequence the seven-garrisons region, including
77 Dunhuang city, was abandoned. The re-opening of the Maritime Silk Road in the southern
78 part of Ming territory was suggested to be another cause of the interruption of the Ancient
79 Silk Road on land (Xie et al., 2007; Qian and Jin, 2010; Zhai, 2017). The thriving of the
80 Maritime Silk Road after the voyages of Zheng He (1405-1431 AD) in the South Seas
81 contributed to the shifting of economic and foreign trade centers from inland in the
82 northwest to the coastal ports in the southeast of the Ming domain. Finally, the role of
83 climate change has been proposed as the possible cause for the abandonment of
84 Dunhuang and the closure of the Ancient Silk Road (Zhang et al., 2018). A pollen record
85 from the sediments of Lake Tian'E in the Qilian Mountains reveals the occurrence of a
86 distinctly drier climate during 1350-1600 AD (Zhang et al., 2018). Previous
87 high-resolution tree-ring records from the Qilian Mountains revealed the occurrence of
88 drought in the Hexi Corridor during 1450-1550 AD (Gou et al., 2015a, b; Yang et al.,
89 2014), corresponding to the onset of a cold climate during the Little Ice Age (LIA), during
90 AD 1450-1850 (Mann et al., 2009). However, these tree ring and lake sediment records
91 are from the eastern part of the Hexi Corridor, and there are no reliable paleoclimatic
92 records from the Dunhuang area in the western part.

93 In the present study of the recent paleoenvironmental and human history of the region,
94 we focused on the Duanhuang-Jiayuguan area, which in terms of the physical
95 environment is the most inhospitable section of the Ancient Silk Road, being dominated
96 by sandy and Gobi deserts. In addition, the area has experienced frequent political turmoil
97 and conflicts. First, the results of a detailed sedimentary investigation of Xishawo site
98 (near Dunhuang city) are presented and evaluated. In addition, the relevant available
99 literature is reviewed and a sociopolitical analysis of the historical archives in Dunhuang
100 and the surrounding areas and in Ming China is used to determine the environmental and
101 sociopolitical changes in the area during the study period. Finally, several possible causes
102 of the abandonment of the Dunhuang area and the official closure of the Ancient Silk
103 Road in the early 16th century AD are reviewed.

104 2. Study area

105 The Hexi Corridor (92°21'to 104°45'E, 37°15' to 41°30'N) is located to the north of
106 the Qilian Mountains and south of Beishan Mountain. It is long and narrow and stretches
107 for over 1,000 km from Wushaoling Mountain in the east to the boundary of Gansu and
108 Xinjiang provinces in the west, but it extends for only tens to some hundreds of

109 kilometers in the North-South direction (Fig.1). The area is the zone of climatic
110 interaction between arid Central Asia and monsoon Asia and is climatically characterized
111 by a continental-monsoon climate influenced by both the westerlies and the monsoon. The
112 annual precipitation is no more than ~200 mm but the evaporation ranges from 1,500 mm
113 to 3,000 mm (Huang et al., 2017). The annual temperature is ~0-10 °C. The Hexi Corridor
114 consists of three independent landlocked river systems: the Shule River Basin, the Heihe
115 River Basin, and the Shiyang River Basin, from west to east. The flow of the three rivers
116 is generated by the glaciers of the Qilian Mountains and is consumed in the middle and
117 lower reaches of Owase Lake or in the deserts within the basin. Diverse landscapes of
118 mountains, oases, deserts and Gobi are alternately distributed in the area. The unique
119 topography and location of the Hexi Corridor were largely responsible for its great
120 strategic and military importance to historical dynasties over the past 2,000 years. It was
121 also known as the key routeway (the Ancient Silk Road) for cultural and merchandise
122 exchanges between Chinese and western countries for thousands of years ago until the
123 present.

124

[Fig. 1 is near here]

126

127 The oasis ecological system in arid areas is fragile because of the closed environment,
128 sparse vegetation and water scarcity. However, the bead-like distribution of oases played
129 a crucial role in the exchange of merchandise in Eurasia. Jiayuguan city was the
130 northwestern gateway of the Ming domain and a key fortress along the routeway of
131 East-West economic exchange. Dunhuang city and Guazhou city (~120 km northeast of
132 Dunhuang) are located in the eastern Gobi Desert to the west of Jiayuguan pass (Fig. 1).
133 The Ancient Silk Road split into three branches in a westerly direction from the region.
134 The northern branch led to the northwest of Hami oasis and the oasis cities of **Turfan**,
135 Yanqi, Qiuci and Gumo, and then to Central Asia. The central branch passed through
136 Loulan city (300 km west of Dunhuang) which was abandoned in ~330 AD because of
137 eolian activity (Yuan and Zhao, 1999; James, 2007; Fontana et al., 2019). The southern
138 branch connected many cities along the southern edge of the Taklimakan Desert, such as
139 Ruoqiang, Qiemo, and Yutian, on the northern piedmont of the **Altyn-Tagh** and the
140 Kunlun Mountains (Fig. 1). As can be seen in Fig. 1, the location of Dunhuang oasis led
141 to its importance as the only logistical station between Hami oasis/Ruoqiang oasis and
142 Jiayuguan oasis during the Ming dynasty.

143 The XSW section in this study is located near the ancient city of Xishawo in the
144 modern Gobi Desert area of the Shule River Basin. The site is in the middle of the

145 Dunhuang and Guazhou oasis, ~50 km northeast of Dunhuang city (Fig. 1). Xishawo site
146 was previously an ancient oasis with cultural sites, ancient cities and beacon towers.
147 Relict river channels are present at some locations, although most of them are buried by
148 sand dunes (Li, 1990; Cheng, 2007). The modern annual mean precipitation and annual
149 mean temperature of the area are 45.3 mm and 8.8° C, respectively. Previous study
150 reveals that the Xishawo site was occupied during between ~900-1400 AD, and local
151 human consumed barley, broomcorn and foxtail millets during that period (Li et al., 2017).
152 Wind-eroded landforms are common in the region as a consequence of the arid climate,
153 sparse vegetation and frequent sandstorms. The exposed part of the XSW section is ~3-m
154 thick and consists mainly of a sand dune which is fixed by the dead roots of *Salix* and
155 therefore preserved. The surface of the profile was cleaned to remove contamination by
156 modern sediments and plant roots. The stratigraphic description of XSW section from the
157 top to 270-cm depth is as follows: (1) 0-10 cm, fine sand. (2) 10-46 cm, dark-gray
158 paleosol, with a 4-cm-thick black cultural layer at 30-34 cm. (3) 46-100 cm,
159 light-yellowish loess. (4) 100-125 cm, loess-like paleosol. (5) 125-185 cm, dark gray clay
160 with Fe-Mn nodules. (6) 185-250 cm, yellow fine sand. (7) 250-270 cm, black silty clay.
161 A total of 135 samples were collected at a 2-cm interval for measurements of weight
162 loss-on-ignition (LOI), grain size, and element contents. One wood sample (at the depth
163 of 10 cm, labeled XSW-10) and one charcoal sample (from the cultural layer at 32 cm,
164 labeled XSW-32) were collected for accelerator mass spectrometry radiocarbon (AMS ¹⁴C)
165 dating. Two eolian samples for optically stimulated luminescence (OSL) dating from the
166 fine yellow sand layer (188 cm and 248 cm, labeled XSW-188, XSW-248, respectively)
167 were collected by hammering stainless-steel cylinders into the section vertically, which
168 were immediately sealed with opaque tape after removal.

169 3. Methodology

170 3.1 Laboratory analyses

171 (1) Chronology

172 AMS ¹⁴C and OSL dating were used to establish a chronological framework for the
173 XSW section. The charcoal and wood samples for AMS ¹⁴C dating was prepared by the
174 acid-base-acid procedure at the MOE Key Laboratory in Lanzhou University and
175 measured at the AMS ¹⁴C dating laboratory of Peking university. The IntCal13 curve,
176 Libby half-life of 5,568 years and OxCal 4.2 were used to calibrate all of the dates
177 (Reimer et al., 2013). All ages reported are relative to 1950 AD (referred to as “cal BC”
178 and “cal AD”).

179 OSL dating was conducted at the OSL Laboratory at the MOE Key Laboratory of
180 Western China's Environmental System, Lanzhou University. Two OSL dating samples
181 were collected from the XSW section. The pretreatment procedure followed that
182 described in Aitken (1998). OSL measurement of coarse-grained (90-125 μm) quartz were
183 performed using an automated Risø TL/OSL DA-20 reader. Laboratory irradiation was
184 carried out using $^{90}\text{Sr}/^{90}\text{Y}$ sources. The quartz OSL signal was detected by a
185 photomultiplier tube through two 3-mm-thick Hoya U-340 filters and the K-feldspar IRSL
186 signal was detected using a package of Corning7-59 and BG-39 filters. The purity of the
187 quartz extracts was checked by the IR depletion ratio test (Duller et al., 2003). A single
188 aliquot regenerative protocol (Murray and Wintle, 2003) was applied to quartz samples to
189 obtain the equivalent dose (De). The concentrations of the radioactive elements uranium
190 (^{238}U), thorium (^{232}Th) and potassium (^{40}K) were measured by neutron activation analysis
191 (NAA) to calculate the dose rate. The cosmic ray contribution was calculated according to
192 the burial depth and altitude of the samples (Prescott and Hutton, 1994). A water content
193 of $10 \pm 5\%$ was used to the calculate ages of sand-loess sediments.

194 (2) Analysis of climatic proxies

195 Measurements of LOI, grain size and element contents were made at the MOE Key
196 Laboratory of Western China's Environmental System Lanzhou University. LOI
197 measurements were used to determine the organic matter content of the sediments. The
198 measurements were made at a 2-cm interval and calculated as LOI_{550}
199 $(\%) = (m_{105} - m_{550}) / m_{105} \times 100\%$, where m_{105} is the sample weight after oven drying at 105°C ,
200 and m_{550} is the sample weight after combustion at 550°C for 4 hr in a muffle furnace.

201 Samples for grain-size analysis were pre-treated with 10% H_2O_2 and 10% HCL to
202 remove organic matter and carbonates, respectively. The samples were then dispersed by
203 ultrasonication with the addition of 10% sodium hexametaphosphate. Grain-size
204 distributions were measured with a Malvern MS 2000 laser grain-size analyzer.

205 Samples for the analysis of element contents were pretreated as follows. All samples
206 were oven-dried for 24 hr and then pulverized into a powder. About 4 g of powder was
207 then pressed into a 4-6-mm-thick and 30-mm-diameter pellet under 30 t/m^2 of pressure.
208 The major, minor and trace element contents were measured with a Magix PW2403
209 Wavelength-Dispersive XRF Spectrometer. Elemental concentrations of 0.1 ppm to 100%
210 could be analyzed. Rb/Sr ratios were calculated for paleoenvironmental reconstruction.

211 3.2 Analysis of published paleoenvironmental records and documentary evidence for the 212 region

213 (1) Previous paleoclimatic records from the region

214 All available high-resolution paleoclimatic records for the studied area and the
215 adjacent region were reviewed and compared. They include records of regional
216 temperature, precipitation, and river flow. In addition, documentary evidence of climate
217 change in the region during the Ming dynasty was investigated.

218 (2) Sociohistorical archives

219 Sociohistorical records such as of the politics and economic and military activity of
220 the Ming dynasty were analyzed (Zhang, 1974; Chinese Military History Writing Group,
221 2003; Yu, 2003), together with sociohistorical records of the Jiayuguan-Dunhuang area.

222 4. Results and discussion

223 4.1. Closure and re-opening of the Jiayuguan Pass and the maritime trading ban

224 Analysis of historical archives demonstrates that the Jiayuguan Pass was first closed
225 in 1524 AD and finally closed in 1539 AD. This was followed by the abandonment of
226 Dunhuang city in 1539 AD, which marked the decline of the Ancient Silk Road on land.
227 However, although maritime trade was banned at the beginning of the Ming dynasty
228 (1370 AD), the ban was lifted in 1567 AD, which resulted in the flourishing of the
229 maritime Silk Road in the late Ming dynasty (Zheng, 1985; Liu, 2014). The lifting of the
230 ban on maritime trade in 1567 AD cannot have been the cause of the decline and closure
231 of the land Silk Road in 1539 AD, as the effect could not precede the cause. On the other
232 hand, the only sea trade route was that used during the seven official voyages of Zheng
233 He (1405-1433 AD), during the period of the maritime trading ban (1370-1567 AD),
234 which needs to be investigated (Dreyer, 2006).

235 At the beginning of the Ming Dynasty (Hongwu year), new diplomatic and security
236 risks in the southeast coastal region threatened the emperor's dominance (Gu, 1977). In
237 1371 AD, the founder of the Ming dynasty, Zhu Yuanzhang, assembled 111, 730 soldiers
238 to establish commanderies which were designed to prevent any private maritime trading
239 (Research Institute of History and Language of the Central Academy in Taiwan, 1962).
240 This policy was intended to counter incursions by Japanese pirates, to promote tribute
241 trade, and to stabilize the social conditions on the southeast coast and maintain the
242 autocratic governance of China. In addition, "Huairou's cultural policy" was implemented
243 by the ruling regime. This policy involved the Ming government providing goods in
244 return which were of much greater value than those supplied by the tribute trade. The aim
245 of Zheng He's voyages (1405-1433 AD) in the Yongle year was to establish diplomatic
246 relations with foreign countries and to promote the image of a powerful Ming government

247 overseas (Gu, 1977). Although this policy helped boost the international reputation of the
248 Ming government, it resulted in a substantial fiscal deficit. Therefore, the voyages of
249 Zheng He were conducted for reasons of national prestige and they did not represent
250 genuine profit-driven trading activity along the maritime Silk Road.

251 The ban on maritime trade not only resulted in dire poverty among the inhabitants of
252 the southeast coast, but it also caused the Ming government to lose a huge amount of
253 income from maritime trade. The maritime trade restriction lasted for about two hundred
254 years until it was lifted by the Longqing emperor in 1567 AD (the first year of the reign of
255 Longqing) at the port of Yue in Zhangzhou, Fujian Province (Chen, 1962). From then
256 onwards, the maritime trading activity of the Ming dynasty developed rapidly and private
257 foreign trade was revived and began to flourish. Furthermore, it helped develop connect
258 domestic and international markets for the Ming dynasty (Liang, 1989).

259 In summary, the previous assumption that the maritime trade policy of the Ming
260 dynasty was responsible for the decline of the Ancient Silk Road on land is incorrect.
261 Before 1567 AD, the Ming continued the ban on maritime trade which impoverished both
262 the government and the common people. The voyages of Zheng He represented the desire
263 of the rulers of China to establish political connections with foreign countries and not to
264 promote trade and economic development. After the lifting of the ban in 1567 AD, private
265 citizens in the southeast coast started to carry out maritime trade, with the result that the
266 economy began to revive. However, the abandonment of Dunhuang and the interruption
267 of the Ancient Silk road occurred in 1539 AD, decades before the cancellation of the
268 maritime trade ban. In addition, Zheng He's voyages ended more than a century before
269 the official closure of the Jiayuguan Pass.

270 4.2. Effects of warfare on the Ancient Silk Road

271 Frequent warfare in the northwestern part of the Ming domain was suggested to be
272 another reason for the repeated (twice) closure of the Jiayuguan Pass and the severance of
273 the Ancient Silk Road (Gao and Zhang, 1989; Chen, 2011). The Jiayuguan Pass was
274 established in 1372 AD in the early Ming dynasty to resist the remaining elements of the
275 Yuan dynasty (1271-1368 AD), and the Hexi Corridor was under the total control of the
276 Ming government during the Ming dynasty. In addition, the Ming dynasty government
277 established seven garrisons in the west of Jiayuguan Guan to reduce pressure on the
278 border (Zhang, 1974). The Jiayuguan Pass was not only a military fastness, but also the
279 primary pass on the Ancient Silk road to the Western Regions.

280 In order to investigate the relationship between conflict and the closure of the
281 Jiayuguan Pass, the frequency of agri-nomadic conflict in the Dunhuang area was
282 estimated based on historical archives (Chinese Military History Writing Group, 2003; Yu,

283 2003). The incidence of agri-nomadic conflicts in the Hexi Corridor was also summarized
284 for comparison (Fig. 2). The classification of agri-nomadic conflict was adopted because
285 it directly reflects the conflict between the central government and nomadic peoples (Fig.
286 2a). The frequency of tribute trade and the number of tribute states in the Western
287 Regions are illustrated in Fig. 2b and 2c (Chinese Military History Writing Group, 2003; Yu,
288 2003). All of the data were grouped into 5-year intervals. It is evident that conflicts
289 between agriculturalists and nomads occurred constantly from 1368 AD, in the early
290 Ming dynasty, until 1520 AD. However, conflicts ceased in the Dunhuang area after 1520
291 AD, which shows that the final closure of the Jiayuguan Pass in 1539 AD substantially
292 reduced the frequency of nomad incursions in the Dunhuang area. However, evidence is
293 still needed to prove that agri-nomadic conflicts were responsible for the closures of the
294 Jiayuguan Pass in 1524 AD and 1539 AD, and the decline of the Ancient Silk Road. For
295 example, it is unclear why -- if agri-nomadic conflicts no longer occurred after 1520 AD
296 -- the Jiayuguan Pass was closed decades later in 1539 AD. It is also unclear why there
297 was a lull in political unrest and violence in the Dunhuang area from 1450 AD.

298

299

300

[Fig. 2 is near here]

301

302

303 Reference to Fig. 2b and 2c shows that tribute exchange between the Ming
304 government and the Western Regions has almost no relationship with the frequency of
305 conflicts. The tribute trade frequency and the number of tribute states both reached a peak
306 during 1400-1450 AD, but then decreased sharply after 1450 AD and subsequently
307 maintained a low level. As Fig. 2a demonstrates, there were frequent agri-nomadic
308 conflicts during 1400-1450 AD, which were followed by a truce which lasted for about 20
309 years. However, the tribute trade declined substantially during the truce (1450-1470 AD)
310 and there was no obvious revival until the collapse of the Ming dynasty (Fig. 2b and Fig.
311 2c).

312 It has been determined that the Jiayuguan Pass-Dunhuang city route was the crucial
313 routeway connecting the Western Region to the domestic territory during the Ming
314 dynasty (Zhang, 1974). The absence of a relationship between the frequency of wars in
315 the Dunhuang area and variations in the amount of tribute trade demonstrates that warfare
316 was not the primary of the collapse of trade along the Ancient Silk Road trade. Moreover,
317 war was not solely responsible for the closure of the Jiayuguan Pass. The first closure of
318 the Jiayuguan Pass in 1524 AD may have been a consequence of wars in the Dunhuang
319 area, although wars also frequently occurred during periods in which trade flourished

320 (1400-1450 AD) (Fig. 2a). However, subsequently there was a continuous state of peace
321 in the Dunhuang area which lasted for decades and the city was only abandoned by the
322 final closure of the Jiayuguan Pass in 1539 AD. Therefore, we conclude that warfare was
323 not the tenable explanation for the **decline** of the Ancient Silk Road.

324 4.3. Influence of climate change on the Ancient Silk Road

325 **Climate change has been attributed as an important and sometimes critical trigger for**
326 **the rise and fall of ancient civilizations on the Ancient Silk Road or proto-Silk Road**
327 **(Fontana et al., 2019, Tan et al., 2020). Generally, climate change will not directly lead to**
328 **historical societal impacts, but the ecological deterioration will trigger subsistence**
329 **pressures or other social and economic adjustments (White and Pei, 2020). It's a complex**
330 **mechanism and needs to be investigated. Therefore, whether the relationship between**
331 **climate change and the abandonment of Dunhuang city during the later Ming dynasty was**
332 **exist, or whether climatic deterioration was responsible for local desertification and the**
333 **cessation of trading along the Ancient Silk Road were discussed.**

334 4.3.1 Paleoclimatic record of the XSW section

335 The paleoclimatic record of the XSW section in the Dunhuang area was used to
336 assess the possible role of climate change in the decline of the Ancient Silk Road. The
337 results of the analysis of various climatically-sensitive parameters, together with the ^{14}C
338 and OSL chronology, are illustrated in Fig. 3. The ^{14}C dates for the fine sand layer
339 (XSW-10) and the cultural layer (XSW-32) are 499 ± 10 cal yr BP (1440-1460 cal AD) and
340 701 ± 27 cal yr BP (1224-1278 cal AD), respectively. The two OSL samples from the sand
341 layer are dated to 2.6 ± 0.2 ka (800 ± 300 BC) and 2.8 ± 0.2 ka (600 ± 200 BC) (Table 2).
342 Profiles of grain size, LOI and Rb/Sr ratio are shown in Fig. 3a, 3b, 3c and 3d,
343 respectively. The increase in median grain size and of the >63 μm fraction indicate an arid
344 environment and intense wind activity in the Dunhuang area during 800-600 BC and at
345 ~ 1450 AD. The LOI record reflects variation in organic matter content and the Rb/Sr ratio
346 of eolian sediments is positively correlated with weathering intensity. The Rb/Sr ratio of
347 the two sand layers is very low (Fig. 3), and therefore the effects of weathering are minor
348 (Gallet et al., 1996; Chen et al., 1999), suggesting that precipitation in the Dunhuang area
349 was low during ~ 800 -600 BC and after ~ 1450 AD. A comparison of the LOI and Rb/Sr
350 profiles indicates that during 800-600 BC and after ~ 1450 AD, the organic matter content
351 of the section was low and chemical weathering was weak. These results suggest the
352 occurrence of overall arid conditions, frequent dust storms, and associated desertification
353 events during 800-600 BC, i.e. **the Spring and Autumn period (771 to 476 BCE) of the**

354 **Eastern Zhou Dynasty**, and after ~1450 AD (the Ming dynasty). These conditions would
355 have been very unfavorable for human habitation of the area.

356

357

[Fig. 3 is near here]

358

359 The two desertification events recorded in the XSW section were not solely local
360 events. A cold and dry climate at these times is also evident in palaeoclimatic records
361 from the nearby Qilian mountain and the Tibetan Plateau. A tree ring record from the
362 Qilian Mountains suggests that precipitation was low during 900-550 BC (Yang et al.,
363 2014). A pollen record from Juyanze lake indicates the low representation of tree pollen at
364 the same time (Herzschuh et al., 2004). The $\delta^{18}\text{O}$ record from the Agassiz ice cap in the
365 high Arctic indicates relatively low temperatures during ~800-600 BC (Lecavalier et al.,
366 2017), which is correlative with records from the Guliya ice core in the Tibetan Plateau
367 (Thompson et al., 1997). The timing of the second desertification event in the Dunhuang
368 area, in ~1450 AD (Fig. 2), coincides well with changes in a tree-ring record from
369 mountains in the western Hexi corridor, which suggests an interval of persistent low
370 precipitation during **1430-1540 AD** (Gou et al., 2015a). An interval of reduced
371 precipitation during this time is also widely recorded in other high-resolution tree ring
372 records from the northern Tibetan Plateau (Gou et al., 2015b; Yang et al., 2014), and in
373 the laminated sediments of Sugan lake in the western Qaidam Basin (Qiang et al., 2005).
374 A decrease in global temperature at ~1450 AD has also been widely detected in
375 high-resolution paleoclimate records from various locations (Thompson et al., 1997;
376 Wilson et al., 2016; Lecavalier et al., 2017), and is recorded in historical documentary
377 records from China (Ge et al., 2003). This evidence indicates that two desertification
378 events in the Dunhuang area and elsewhere, during ~800-600 BC and after ~1450 AD,
379 which were related to regional-scale climatic and environmental deterioration.

380 As mentioned earlier, the oasis ecological system in arid regions is relatively fragile,
381 with the major limit factor being water availability (Qian and Jin, 2010). At the present
382 time vegetation survival in the oasis of the Hexi Corridor is mainly dependent on runoff
383 from the Qilian Mountains, which is derived first from precipitation in the highlands and
384 second from glacier meltwater (Liu et al., 2010; Yang et al., 2011; Sakai et al., 2012). The
385 striking long interval of reduced precipitation and temperature in the Qilian Mountains
386 and in the Tibetan Plateau during ~800-600 BC and at ~1450 AD caused a large decrease
387 in runoff to the lowlands of the Hexi Corridor, which in turn caused vegetation
388 degradation and the extension of Gobi and sandy desert. Compared to other oasis cities
389 along the Ancient Silk Road, which were much closer to the high mountain glaciers

390 (above 4,500 m.a.s.l., Fig. 1) which provided a constant supply of meltwater, Dunhuang
391 oasis was located much closer to the center of the Gobi, and therefore it experienced
392 severe desertification which resulted in its abandonment.

393 **4.3.2 *Archaeological evidence of climate change in the Dunhuang area***

394 The relatively dense distribution of prehistoric sites in the Hexi Corridor reflects the
395 past intensity of human settlement in the area (Bureau of National Cultural Relics, 2011)
396 as well as the habitability of the surrounding environment (Yang et al., 2019). The Hexi
397 Corridor was extensively settled from the Majiayao period (3300-2000 BC) (Li, 2011),
398 and foxtail millet and broomcorn millet, which were domesticated in north China, were
399 cultivated (Zhou et al., 2016; Dong et al., 2018). Agricultural technological innovations
400 facilitated the rapid development of Bronze cultures in the Hexi Corridor and the
401 surrounding areas in the succeeding millennium (Dong et al., 2016; Zhou et al., 2016).
402 However, there is a gap in radiocarbon dates during ~850-650 BC in the western Hexi
403 Corridor and eastern Xinjiang Province (Fig. A1), which suggests a hiatus in cultural
404 evolution and exchange during this period. This hiatus corresponds well to the
405 desertification event in the Dunhuang area of the western Hexi Corridor during
406 ~800-600 BC (Fig. 3). However, even though the climate fluctuated substantially in
407 northwest China during the Bronze Age, human settlement was continuous in the eastern
408 Hexi Corridor at the same longitude (Fig. A1), which suggests that human occupation of
409 the Hexi Corridor was primarily determined by the environmental conditions.

410 The second desertification event occurred at ~1450 AD and is recorded both in the
411 sand layer of the XSW profile and in the historical and cultural literature. The drought in
412 the Dunhuang area at this time was described as “The wind shakes the Tamarix in
413 thousands of miles of uninhabited land” and “the moon shines on the quicksand on each
414 departed day” (Huang and Wu, 2008). **The Yugur minority ancestors, who originally
415 settled in the Duanhuang area, after the abandonment of Dunhuang, sang folk songs about
416 the migrations through the Jiayuguan Pass during the Ming dynasty (Chen, 2011).** An epic
417 of the migration of the Yugur minority history contains the following: “Violent winds
418 swept livestock away, sand dunes submerged tents and houses, rivers dried up, grassland
419 was devastated” (Wang, 1992; Editing Group of Brief History for Yugur minority, 2008).
420 From these descriptions it can be deduced that the prolonged drought at around 1450 AD
421 may have led to the disappearance of the oasis. Hence, the altered eco-environment
422 reduced the productivity of agriculture and animal husbandry, which resulted in a local
423 food shortage. The deteriorated environment was very likely another cause of mass
424 migration in addition to warfare. The changing geopolitical situation in the western Hexi

425 Corridor and eastern Xinjiang Province was an important factor in the abandonment of the
426 Dunhuang area by the Ming government, and the extreme and the persistent drought event
427 after ~1450 AD may have intensified the social upheaval and chaos (Fig. 2d), which
428 triggered this significant historical event. Notably, a significant relationship has been
429 observed between decreased precipitation, wars and the abandonment of cultivated land in
430 the region during the last 2,000 years (Li et.al. 2019).

431 ***4.3.3 Desertification events in the ancient Silk Road area***

432 Various indicators of climatic variations, wars and the tribute trade are plotted in
433 Fig. 2 against the chronological sequence of the Ming dynasty (1368-1644 AD). Under
434 the premise that at ~1450 AD the environment was characterized by a cold and dry
435 climate with intense sandstorms (Fig. 2e), low precipitation (Fig. 2f) and decreased
436 streamflow (Fig. 2g), there is a strong possibility that climate change played a role in the
437 decline of the Ancient Silk Road. There was an abrupt decrease in the frequency of tribute
438 trade at ~1450 AD, but not during the two closures of the Jiayuguan Pass, in 1524 AD and
439 1539 AD (Fig. 2b and 2d). In addition, at this time there was a lull in conflicts in the
440 Dunhuang area (Fig. 2a). Therefore, it is proposed that environmental deterioration most
441 likely was the cause of the decline of the tribute trade and the cessation of hostilities.
442 Climatic perturbations and environmental degradation may not necessarily be a direct
443 trigger of a societal crisis, but they may instead result in institutional failure caused by the
444 lack of a centralized response to an environmental crisis (Feng et al. 2019). Social
445 disturbance associated with migrations and chaos in the Ming dynasty (Fig. 2d) was most
446 likely an indirect consequence of environmental changes. For example, the consequences
447 of a deteriorating environment would include a shrinking of the habitat and farmland
448 necessary for human survival, multiple waves of human migrations into the eastern part of
449 the Hexi Corridor, and the shift of the frontier from Dunhuang to the Jiayuguan pass.
450 Thus, the population decline in the Dunhuang area during the early Ming Dynasty was
451 most probably a “domino effect” (Feng et al. 2019).

452 The influence of the desertification in ~1450 AD on the streamflow of the Qilian
453 Mountains gradually decreased after the 1520s AD (Fig. g and Fig. h). However, the
454 formation and evolution of an oasis is a long-term process (Stamp, 1961; Zhang and Hu,
455 2002; Li et al., 2016), and the ecological response of an oasis to climatic drying would not
456 to be to disappear immediately (Fan, 1993). Moreover, it takes at least 15-20 years for the
457 recovery of a degraded oasis following destruction by ~1-3 years’ of human activity
458 (Zhang and Hu, 2002). Therefore, the regeneration of a degraded oasis would take much
459 longer than a change in streamflow. Overall, it is suggested that the ancient Silk Road was

460 declined by the deterioration of the environment along the routeway, and the decline of
461 tribute exchange (Fig. b and Fig. c) indicates an abrupt decrease in the prosperity of the
462 Silk Road in the Ming dynasty.

463 We now address the issue of how desertification at ~1450 AD in the Dunhuang oasis
464 and adjacent regions affect the through efficiency of the Silk Road. First, trading in the
465 arid environment of the ancient Silk Road led to the increase in the importance of oasis
466 cities. Camel caravans needed supplies of grain and water from an oasis as they traversed
467 the extensive desert along the road. The desertification events recorded in the XSW
468 section and in adjacent regions indicate that Dunhuang oasis and Guazhou oasis were not
469 functioning at ~1450 AD. This lengthened the distance from the Jiayuguan oasis in the
470 Hexi Corridor to the western oasis in Xinjiang (Fig. 1). According to several researchers,
471 camel caravans in deserts areas were able to travel a maximum distance of ~30 km/day
472 (Shui, 1990; Wang et al., 2000). In addition, the metabolism of a domesticated camel will
473 decrease within 20 days from the beginning of water deprivation (Chen, 1982). Under
474 working conditions, camels can go for ~10-15 days without water under a mean ambient
475 temperature of 35°C (Kataria et al., 2001). A camel caravan took 59 days to traverse the
476 1,400 km of the Taklimakan Desert in 1993 AD under modern climatic conditions, which
477 were much more favorable than in ~1450 AD, and the maximum distance was 24 km in
478 one day (Blackmore, 2000). The maximum distance for a caravan in the water-limited
479 environment on the Silk Road was $30 \text{ km/day} \times 15 \text{ days} = 450 \text{ km}$. The distances of Hami,
480 Ruojiang and Jiayuguan to Dunhuang, where are Gobi desert without high mountains, are
481 already close to or above this limit, which is barely sufficient for camel travel (shown by
482 the dots in Fig. 1, near Dunhuang and Shazhou oasis). On the other hand, the distances
483 between the oases along the routes on the piedmonts of the high mountain ranges (Qilian,
484 Kunlun and Tianshan) are generally less than 200 km as the high mountain ranges provide
485 melting water. After the desertification event, the distances between Jiayuguan and Hami
486 oases (the northern route of the ancient Silk Road) and between Jiayuguan and Ruoqiang
487 oases (the southern route) increased to ~600 km and ~1,000 km, respectively. This is
488 close to the maximum distance that a camel caravan can achieve (~450 km) without a
489 water supply. This would have added greatly to the difficulty of travel across the region
490 and was likely to be the physical cause of the decline of the Ancient Silk road during the
491 periods of desertification.

492 5. Conclusion

493 We have systematically investigated the possible reasons for the interruption of the
494 operation of the Ancient Silk Road during the Ming Dynasty. The results suggest that

495 neither the rise of the maritime Silk Road nor the effects of warfare provide the best
496 explanation of the severance of exchanges between Western countries and the Ming
497 government. A compilation of the results of absolute dating and high-resolution
498 paleoclimatic records from the SXW site in the Dunhuang area, and historical archives,
499 reveals that two desertification events occurred, at ~800-600 BC and ~1450 AD. The later
500 desertification event caused the destruction of the oases in Dunhuang and Guazhou city,
501 which were strategic logistical stations in the vast Gobi Desert; this resulted in travelling
502 distances between supply stations exceeding the physical limit for camel caravans. As a
503 consequence, chaos and mass migrations occurred between Dunhuang oasis and
504 Jiayuguan oasis during 1495-1528 AD in the Ming Dynasty. The Jiayuguan Pass was
505 finally closed in 1539 AD and Dunhuang city was abandoned. However, the immediate
506 fall in tribute trade occurred in ~1450 AD, long before the chaos and migrations but
507 consistent with the beginning of the desertification event. Therefore, the best available
508 explanation of the decline of the Ancient Silk Road trade was climate-driven
509 desertification.

714 Figure 1. Location of the study area and cities along the Ancient Silk Road (dotted circles
715 are oasis cities which were already abandoned before the Ming dynasty; solid circles
716 are oasis cities which still existed during the Ming dynasty; the cities in parentheses
717 were under Ming governorship; the dotted area is Gobi Desert near Dunhuang and
718 Guazhou) (The base map was captured from ©Google Maps)

719 Figure 2. Comparison of records of wars, climate change and cultural events in the
720 Duanghuang area during the Ming-Qing dynasties. (a) Frequency of agri-nomadic
721 wars in the Dunhuang area. (b) Tribute trade through the Jiayuguan Pass between the
722 Ming government and Western countries. (c) Number of tribute states of Western
723 countries. (d) Major events in the Ming dynasty (blue triangles are mass migrations;
724 red triangles indicate the closure of the Jiayuguan Pass; the green triangle indicates
725 the abandonment of Dunhuang city; the purple triangle indicates the lifting of the
726 trading ban during the Ming dynasty). (e) Grain size (>63- μm fraction) of the XSW
727 section (this study). (f) Tree-ring based precipitation record from the western Qilian
728 Mountains (after smoothing) (Gou et al., 2015a). (g) Tree-ring-based streamflow
729 record from the upper reaches of the Heihe River (after smoothing) (Yang et al.,
730 2012).
