19 **ABSTRACT**

20 Constraints on the evolution of atmospheric CO₂ levels throughout Earth's history are foundational to
21 our understanding of past variations in climate. Despite considerable effort, records vary in their
22 temporal and spatial coverage and estimates of past CO₂ levels do not always converge, and therefore
23 new records and proxies are valuable. Here we reconstruct atmospheric CO₂ values across major
24 climate transitions over the past 16 million years using the boron isotopic composition ($\delta^{11}\text{B}$) of
25 planktic foraminifera from 89 samples obtained from two sites in the West Pacific Warm Pool, Ocean
26 Drilling Program (ODP) Sites 806 and 807 measured using high-precision multi-collector inductively-
27 coupled plasma mass spectrometry. We compare our results to published data from ODP Site 872,
28 also in the Western Equatorial Pacific, that goes back to 22 million years ago. These sites are in a
29 region that today is near equilibrium with the atmosphere and are thought to have been in equilibrium
30 with the atmosphere for the interval studied. We show that $\delta^{11}\text{B}$ data from this region are consistent
31 with other boron-based studies. The data show evidence for elevated pCO₂ during the Middle
32 Miocene and Early to Middle Pliocene, and reductions in pCO₂ of ~200 ppm during the Middle
33 Miocene Climate Transition, ~250 ppm during Pliocene Glacial Intensification, and ~50 ppm during
34 the Mid-Pleistocene Climate Transition. During the Mid-Pleistocene Transition there is a minimum
35 pCO₂ at MIS 30. Our results are consistent with a coupling between pCO₂, temperature and ice sheet
36 expansion from the Miocene to Recent.

37

38 **Highlights**

39 In this study, we reconstruct atmospheric pCO₂ using $\delta^{11}\text{B}$ data from ODP Sites 806 and 807 and
40 compare them with ice core data. We therefore apply the same framework to older samples to create a
41 long-term pH and pCO₂ reconstruction for the past 16 million years, and recalculate pCO₂ for ODP
42 Site 872 from 17 to 22 million years ago. We find major increases in surface water pH and decreases
43 in atmospheric pCO₂ were associated with decreased temperature in the Western Equatorial Pacific,
44 including associated with major episodes of ice sheet expansion in the high latitudes, providing more
45 robust quantitative constraints on the past coupling between pCO₂, temperature, and cryosphere
46 stability.

50 1. Introduction

51 Due to concerns about the long-term consequences of anthropogenic emissions and associated
52 climate change (IPCC, 2014, 2018), efforts have been made to quantify past atmospheric CO₂ and
53 examine past relationships between CO₂ and temperature. Such data are not only critical for
54 **constraining** Earth-system sensitivity (Lea, 2004; Lunt et al., 2010; Pagani et al., 2010; Hansen et al.,
55 2012, 2013, Foster and Rohling, 2013; Schmittner et al., 2011; Tierney et al., 2020), but are also of
56 broad interest to **contextualize** the evolution of climate and geological systems through Earth's **history**
57 (Tripathi et al., 2011; Foster et al., 2017; Tripathi and Darby, 2018). However, discrepancies between
58 proxy reconstructions still exist, including for major climate transitions of the Cenozoic. In particular,
59 there remains a pressing need for robust and higher-resolution atmospheric CO₂ records from **regions**
60 **that** are in equilibrium with the atmosphere.

61 High-resolution and direct determinations of atmospheric CO₂ are available for the last 800
62 **kyr** through analysis of air bubbles extracted from ice-cores, but these records are limited to the
63 **availability** of cores (Petit et al., 1999; Siegenthaler et al., 2005; Lüthi et al., 2008; Bereiter et al.,
64 2015). A **window** into atmospheric CO₂ levels comes from 1 million-year-old blue ice (Higgins et al.,
65 2015) and **from a second snapshot from 1.5 Ma** (Yan et al., 2019). Most reconstructions of CO₂ for
66 prior to 800 ka are based on indirect terrestrial and marine proxies. Stomata indices for fossil leaves
67 (**Van der Burgh, 1993; Royer, 2001**), carbon isotope ratios ($\delta^{13}\text{C}$) of paleosols (Retallak et al., 2009),
68 $\delta^{13}\text{C}$ of **alkenones** (Pagani et al., 2005; Zhang et al., 2013), B/Ca ratios of surface-dwelling
69 foraminifera (Yu and Hönisch, 2007; Foster, 2008; Tripathi et al., 2009, 2011), and boron isotope ratios
70 ($\delta^{11}\text{B}$) of **surface-dwelling foraminifera** (e.g. **Pearson and Palmer, 2000; Hönisch and Hemming,**
71 **2009; Seki et al., 2010; Bartoli et al., 2011; Foster, 2008, 2012; Badger et al., 2013; Foster and**
72 **Sexton, 2014; Greenop et al., 2014; Martinez-Boti et al., 2015a; Chalk et al., 2017; Sosdian et al.,**
73 **2018; Dyez et al., 2018; deLaVega et al., 2020; Greenop et al., 2021; Rae et al., 2021; Raitzsch et al.,**
74 **2021; Shuttleworth et al., 2021**) have been used to estimate atmospheric CO₂.

75 Each of the above proxy methods has sources of systematic errors that we do not attempt to
76 exhaustively document as they have been discussed in-depth elsewhere (e.g., Pagani et al., 2005;
77 **Tripathi et al., 2011; Guillermic et al., 2020**). However, we note that significant developments in the
78 **boron-based** proxies include improvements to the accuracy and precision of measurements using
79 **multi-collector** inductively coupled mass spectrometry (MC-ICP-MS) compared to early work with
80 **negative** thermal ionization **mass spectrometry (N-TIMS)**, where there were large instrumental mass
81 fractionations and challenges with **laboratory intercomparison** (Foster et al., 2013; Farmer et al., 2016;
82 Aggarwal and You, 2017). There was **also** the realization that temperature-dependent K_D to
83 interpreting B/Ca sensitivities observed from the **field of sediment trap, core-top, and downcore**
84 **studies** (Yu and Hönisch, 2007; Foster et al., 2008; Tripathi et al., 2009, 2011; Babila et al., 2010;
85 Osborne et al., 2020) differ from foraminiferal culture experiments (Allen et al., 2011, 2012) and

86 inorganic calcite (Mavromatis et al., 2015); this type of discrepancy has also been observed with other
87 elemental proxies (e.g., Mg/Ca). Such differences may be due to differences in growth rates (Sadekov
88 et al., 2014), ontogenetic changes, a correlation in the field between temperature and other
89 hydrographic variables that obscure robust statistical determination of parameter relationships, culture
90 conditions resulting in organisms being stressed, and/or other factors.

91 The marine CO₂ proxy that appears to be subject to the fewest systematic uncertainties, based
92 on our current understanding, is the boron isotopic composition ($\delta^{11}\text{B}$) of planktic foraminifera as
93 measured using MC-ICP-MS and N-TIMS (Hain et al., 2018). This proxy provides constraints on
94 seawater pH, if temperature, salinity, seawater $\delta^{11}\text{B}$, and the appropriate mono-specific calibration
95 between $\delta^{11}\text{B}_{\text{carbonate}}$ and $\delta^{11}\text{B}_{\text{borate}}$ are constrained (Pearson and Palmer, 2000; Foster et al., 2008;
96 Sosdian et al., 2018; Raitzsch et al., 2018; Guillermic et al., 2020). Seawater pH can be used to
97 calculate seawater pCO₂ if there are constraints on a second parameter of the carbonate system (e.g.
98 alkalinity, DIC). Atmospheric pCO₂ can then be constrained if the site being examined is in air-sea
99 CO₂ equilibrium or if the disequilibrium is known and stable through time.

100 However, there are relatively few studies generating high-precision boron-based records over
101 major climate transitions in the Cenozoic using recent analytical methods and that incorporate our
102 current understanding of the proxy (e.g., Greenop et al., 2014; Martinez-Boti et al., 2015b; Chalk et
103 al., 2017; Dyez et al., 2018; Sosdian et al., 2018; de la Vega et al., 2020; Rae et al., 2021; Raitzsch et
104 al., 2021). Furthermore, of the existing studies using boron-based proxies, an additional uncertainty
105 frequently exists, namely the short time interval of study (e.g., emphasizing on a climate transition)
106 (Martinez-Boti et al., 2015b; Chalk et al., 2017) and whether the study sites remain in air-sea CO₂
107 equilibrium with the atmosphere (Martinez et al., 2015a). And although estimation of atmospheric
108 pCO₂ from seawater pH using this proxy is relatively straightforward, reconstructions are still
109 impacted by uncertainties including the lack of robust constraints on a second parameter of the
110 carbonate system, and our limited understanding of secular variations in the $\delta^{11}\text{B}$ of seawater (Tripathi
111 et al., 2011; Greenop et al., 2017; Sosdian et al., 2018; Rae et al., 2021).

112 Therefore, to provide additional constraints on the evolution of atmospheric pCO₂ from the
113 Miocene through Pleistocene, we developed new records from the western tropical Pacific. We use
114 foraminiferal $\delta^{11}\text{B}$ and trace elements in the planktic foraminiferal species *Trilobus sacculifer* and
115 *Globigerinoides ruber* to reconstruct past seawater pH and atmospheric CO₂ at Ocean Drilling
116 Program (ODP) Sites 806 and 807 in the Western Equatorial Pacific (WEP) over the last 16 million
117 years (Myr). The sites are located on the western border of the tropical Pacific Ocean, the largest
118 open-oceanic region on the globe, and the warmest open ocean region at present.

119 These two sites have been examined in other boron-based studies (Wara et al., 2003; Tripathi et
120 al., 2009, 2011; Shankle et al., 2020), as has the region more broadly (Pearson and Palmer, 2000;
121 Sosdian et al., 2018), because it is understood to be in equilibrium with the atmosphere and have

122 relative stable hydrography. The region experiences equatorial divergence but is not strongly affected
123 by upwelling and has a current estimated annual air-sea CO₂ difference of +28 ppmv (Takahashi et
124 al., 2014). The pre-industrial air-sea CO₂ difference is calculated to be +16 ppm, (GLODAP database
125 corrected from anthropogenic inputs), with a value of 298 ppm, compared to the ice core value of 282
126 ppm at 1.08 ka. This pCO₂ difference is similar to our pCO₂ uncertainty (an average of ~17 ppm (2
127 SD) for the youngest samples). If trade winds were much stronger, and equatorial divergence greater,
128 than this could drive some disequilibrium in the past. However, a few lines of evidence suggest the
129 region was in quasi-equilibrium in the past: 1) zonal temperatures are at a maximum in pre-industrial
130 times and during the Pleistocene, and we are able to reconstruct atmospheric pCO₂ values from the ice
131 cores, 2) temperature proxies indicate the region is relatively stable with respect to temperature
132 compared to other parts of the ocean, and also indicate a weak and stable zonal temperature gradient
133 during the Miocene and Pliocene which would support air-sea stable conditions and air-sea
134 equilibrium (e.g., Nathan and Leckie, 2009; Zhang et al. 2014; Liu et al., 2019).

135 Thus, this study builds on low-resolution prior reconstructions for these sites (Wara et al.,
136 2003; Tripathi et al., 2009, 2011; Shankle et al., 2020), Site 872 in the tropical Pacific (Sosdian et al.,
137 2018), and other published boron isotope work, to provide additional data to constrain past seawater
138 pH and pCO₂ for the WEP using MC-ICP-MS, thereby providing a new perspective on reconstructing
139 past atmospheric CO₂ via marine sediment archives. We explore various constraints on the second
140 carbonate system parameter using a number of different scenarios, following on the systematic work
141 done by Tripathi et al. (2009) and (2011) for B/Ca. We interpret these data using recent constraints on
142 seawater δ¹¹B (Lemarchand et al., 2000; Raitzsch and Hönisch, 2013; Greenop et al., 2017). For
143 temperature estimation, we utilize a multi-variable model for Mg/Ca correcting from salinity, pH and
144 seawater Mg/Ca (Gray and Evans, 2019), that builds on prior work with clumped isotopes in planktic
145 foraminifera for Site 806 and other WEP sites demonstrating that for the Last Glacial Maximum to
146 recent, salinity-corrected Mg/Ca values are needed to yield convergent estimates of mixed-layer
147 temperatures (Tripathi et al., 2014).

148

149 2. Materials and Methods

150 Below we describe site locations, analytical methods used, and principal figures. The
151 supplemental methods section describes screening for potential contamination, equations used for
152 calculations, and error propagation.

153

154 2.1 Site locations

155 Samples are from three ODP holes recovered during Leg 130 in the WEP (Fig. 1, Table 1):
156 Hole 806A (0°19.140'N, 159°21.660'E, 2520.7 m water depth), Hole 806B (0°19.110'N,
157 159°21.660'E, 2519.9 m water depth), and Hole 807A (3°36.420'N, 156°37.500'E, 2803.8 m water

158 depth) (Berger et al., 1993). Sites 806 and 807 are not likely to have experienced major tectonic
159 changes over the last 20 million years.

160 161 **2.2 Preservation**

162 Microfossils in sediments at these sites, as with any sedimentary sequences, have the potential
163 to be influenced by diagenesis. Despite evidence of authigenic carbonate formation, recent modeling
164 work concluded the influence of dissolution and reprecipitation at Sites 806 and 807 was relatively
165 minor (Mitnik et al., 2018). Prior work has also found minimal impacts on the B/Ca ratio of Pliocene
166 foraminifera from Site 806 (White and Ravelo, 2020), and on the Mg/Ca ratio of Miocene *D. altispera*
167 shells at Site 806 (Sosdian et al., 2020). The weight/shell ratio is commonly used to monitor
168 dissolution, and the only published record at Site 806 for the Pliocene does not show a trend
169 consistent with dissolution of *T. sacculifer* (Wara et al., 2005). We do note that while the “coccolith
170 size-free dissolution” index reported in Si and Rosenthal (2019) indicates higher dissolution rates in
171 the Miocene, their records were thought to be biased from changes in foraminifera assemblages as
172 discussed in White and Ravelo (2020).

173 To further assess the potential impact of dissolution in our geochemical data, the weight/shell
174 ratio was examined in our samples. The weight/shell data used to monitor dissolution does not exhibit
175 any trend within the interval studied consistent with dissolution. Absolute weights/shell are increasing
176 in the Miocene, which is not consistent with dissolution influencing the record (Fig. 2E).
177 Additionally, reconstructed pH and pCO₂ values also exhibit reasonable correspondence with the ice
178 core data. Downcore δ¹¹B values from Sites 806 and 807 are similar, despite evidence for higher
179 authigenic carbonate at Site 807 relative to Site 806 (Mitnik et al., 2018). Further, despite different
180 sedimentation rates, our δ¹¹B and Mg/Ca results are consistent between Sites 806 and 807, and with
181 data from Site 872 (Sosdian et al., 2018), which implies that diagenesis is not a primary driver of the
182 reconstructed trends. Comparison of raw data, and derived parameters, is shown in Figs. 2 and 7.

183 184 **2.3 Age models**

185 The age model for Site 806 from 0-1.35 Ma is based on Medina-Elizalde and Lea (2005);
186 calculated ages correspond well with ages from the Lisiecki and Raymo LR04 stack (Fig. 2A). The
187 fourth polynomial regression-based biostratigraphy from Lear et al. (2015) was used for the rest of the
188 record, following other work (Sosdian et al., 2020). Ages for Site 807 are based on published
189 biostratigraphy (Berger et al., 1993) with additional constraints placed by Zhang et al. (2007) for the
190 interval from 0-0.55 Ma. Benthic δ¹⁸O values from Sites 806 and 807 show good correspondence for
191 the last 0.55 Myr, and the low-resolution benthic δ¹⁸O record for Site 806 (Lear et al., 2003; 2015) is
192 consistent with the stack from Lisiecki and Raymo, (2005) for the period studied (Fig. 3).

193

194 **2.4 Species and trace element cleaning**

195 Samples were picked and cleaned to remove clays at UCLA (Los Angeles, CA) and the
196 University of Western Brittany (Plouzané, France). 50-100 foraminifera shells were picked from the
197 300-400µm fraction size for *T. sacculifer* (w/o sacc) and from the 250-300 µm for *G. ruber* (white
198 sensu stricto). Picked foraminifera were gently crushed, clays removed, and checked for coarse-
199 grained silicates. Samples were then cleaned using a full reductive and oxidative cleaning protocol
200 following Barker et al. (2003). A final leach step with 0.001N HCl was done prior dissolution in 1N
201 HCl. Boron purification used a published microdistillation protocol (see Misra et al., 2014b,
202 Guillermic et al., 2020 for more detailed methods).

203

204 **2.5 Chemical purification and geochemical analysis**

205 Chemical separation was performed in a boron-free clean lab at the University of Cambridge
206 (Cambridge, UK). Calcium concentrations were measured on an ICP-AES @Ultima 2 HORIBA at the
207 Pôle Spectrometrie Océan (PSO), UMR6538 (Plouzané, France). Elemental ratios (e.g. X/Ca ratios)
208 were analyzed on a Thermo Scientific @Element XR HR-ICP-MS at the PSO, Ifremer (Plouzané,
209 France). Boron isotopic measurements were carried out on a Thermo Scientific @Neptune+ MC-ICP-
210 MS equipped with 10¹³ Ohm resistor amplifiers (Lloyd et al., 2018) at the University of Cambridge
211 (Cambridge, UK).

212

213 **2.6 Standards**

214 Variations in B isotope ratios are expressed in conventional delta (δ) notation with δ¹¹B values
215 reported against the reference standard NIST SRM 951 (NIST, Gaithersburg, MD, USA):

$$216 \quad \delta^{11}\text{B} (\text{‰}) = 1000 \times \left(\frac{{}^{11}\text{B}/{}^{10}\text{B}_{\text{Sample}}}{{}^{11}\text{B}/{}^{10}\text{B}_{\text{NIST SRM 951}}} - 1 \right) \quad \text{eq. 1}$$

217 Multiple analyses of external standards were performed to ensure data quality. For boron
218 isotopic measurements, JCp-1 (Geological Survey of Japan, Tsukuba, Japan, Gutjahr et al., 2020) was
219 used as a carbonate standard, and NEP, a *Porites sp* coral from University of Western Australia and
220 Australian National University was also used (McCulloch et al., 2014). A boron isotope liquid
221 standard, ERM[®] AE121 (certified δ¹¹B = 19.9 ± 0.6 ‰, SD), was used to monitor reproducibility and
222 drift during each session (Vogl and Rosner, 2012; Foster et al., 2013; Misra et al., 2014b). For trace
223 elements, external reproducibility was determined using the consistency standard Cam-Wuellerstorfi
224 (University of Cambridge) (Misra et al., 2014b).

225

226 2.7 Figures of Merit

227 2.7.1 $\delta^{11}\text{B}$ analyses

228 Samples measured for boron isotopes typically ranged in concentration from 10 ppb B (~5ng
229 B) to 20 ppb B samples (~10ng B). Sensitivity was 10mV/ppb B (eg. 100mV for 10ppb B) in wet
230 plasma at 50 $\mu\text{l}/\text{min}$ sample aspiration rate. The intensity of ^{11}B for a sample at 10 ppb B was typically
231 104 ± 15 mV (2 SD, typical session) and closely matched the 98 ± 6 mV (2 SD, typical session) of the
232 standard. Procedural boron blanks ranged from 15 pg B to 65 pg B (contributed to less than 1 % of the
233 sample signal). The acid blank during analyses was measured at ≤ 1 mV on the ^{11}B (which also is < 1
234 % of the sample intensity), and no memory effect was seen within and across sessions.

235 External reproducibility was determined by analyzing the international standard JC_{P.1}
236 (Gutjahr et al., 2020) and a *Porites sp.* coral (NEP). The boron isotopic composition of JC_{P.1} was
237 measured at 24.06 ± 0.20 ‰ (2 SD, n=6) within error of published values of 24.37 ± 0.32 ‰, $24.11 \pm$
238 0.43 ‰ and 24.42 ± 0.28 ‰ from Holcomb et al. (2015), Farmer et al. (2016) and Sutton et al. (2018),
239 respectively. Average values are $\delta^{11}\text{B}_{\text{NEP}} = 25.72 \pm 0.79$ ‰ (2 SD, n=31) determined over 13 different
240 analytical sessions, with each number representing a separately processed sample from this study.
241 These results are within error of published values of 26.20 ± 0.88 ‰ (2 SD, n = 27) and 25.80 ± 0.89
242 ‰ (2 SD, n = 6), from Holcomb et al. (2015) and Sutton et al. (2018), respectively. Data are reported
243 in Supplementary Table B.

244

245 2.7.2 X/Ca analyses

246 Trace element (TE) analyses were conducted at a Ca concentration of either 10 or 30 ppm.
247 Typical blanks for a 30 ppm Ca session were: $^7\text{Li} < 2$ ‰, $^{11}\text{B} < 7$ ‰, $^{25}\text{Mg} < 0.2$ ‰ and $^{43}\text{Ca} < 0.02$ ‰.
248 Additionally, blanks for a 10 ppm Ca session were: $^7\text{Li} < 2.5$ ‰, $^{11}\text{B} < 10$ ‰, $^{25}\text{Mg} < 0.4$ ‰ and $^{43}\text{Ca} <$
249 0.05 ‰. Analytical uncertainty of a single measurement was calculated from the reproducibility of the
250 CamWuellestorfi standard: 0.6 $\mu\text{mol}/\text{mol}$ for Li/Ca, 8 $\mu\text{mol}/\text{mol}$ for B/Ca and 0.02 mmol/mol for
251 Mg/Ca (2 SD, n=48). Data are reported in Supplementary Table B.

252

253 2.8 Calculations

254 Detailed calculations can be found in the supplemental materials. Briefly, Mg/Ca was used to
255 reconstruct sea surface temperature (SST) using the framework from Gray and Evans. (2019)
256 correcting for influences of pH, salinity, and secular variation in seawater Mg/Ca. $\delta^{11}\text{B}_{\text{carbonate}}$ was
257 corrected using an empirical $\delta^{11}\text{B}_{\text{carbonate}}$ -weight/shell ratio relationship. $\delta^{11}\text{B}_{\text{borate}}$ was determined using
258 species dependent sensitivities of $\delta^{11}\text{B}_{\text{carbonate}}$ to $\delta^{11}\text{B}_{\text{borate}}$ (Guillermic et al., 2020). pH was calculated
259 using the $\delta^{11}\text{B}_{\text{borate}}$ with different scenarios of secular seawater $\delta^{11}\text{B}$ changes (Lemarchand et al., 2002;
260 Raitzsch and Hönisch, 2013; Greenop et al., 2017). pCO_2 was reconstructed using pH based

261 $\delta^{11}\text{B}_{\text{carbonate}}$ and different scenarios of alkalinity (Tyrell and Zeebe, 2004; Ridgwell and Zeebe, 2005;
262 Caves et al. 2016 and Rae et al. 2021). Further details including equations are in the Supplement.

263

264 3. Results and discussion

265 3.1 Geochemical results

266 Geochemical data used in this study are presented in Figure 2. Mg/Ca data (Fig. 2C) are
267 consistent with previously published Mg/Ca values for Site 806 on *T. sacculifer* (Wara et al., 2005;
268 Tripathi et al., 2009; Nathan and Leckie, 2009). Although the record we generated does not overlap
269 with Site 872, they are 1 myr apart (15.7 and 16.7 Ma); there is a good correspondence between our
270 Mg/Ca data and the published Mg/Ca record from *T. trilobus* at Site 872 (Sosdian et al., 2018). Mg/Ca
271 from a different species, *D. altispira* (Sosdian et al., 2020), is also plotted with an offset, for
272 comparison.

273 Comparison with Site 872 data that is part of the compilation from Sosdian et al. (2018)
274 shows that their $\delta^{11}\text{B}$ data are in line with our dataset (Figure 2B), and all sites examined in the WEP
275 (Sites 806, 807, and 872) are above the lysocline (Kroenke et al. 1991). The $\delta^{11}\text{B}$ data for *T. sacculifer*
276 exhibit a significant decrease (4.2 ‰) from the Miocene to present. Figure 2B also compares the $\delta^{11}\text{B}$
277 data used in this study with published data from other sites and shows that raw $\delta^{11}\text{B}$ data for the WEP
278 can be lower than values for other regions.

279

280 3.2 Reproducing pCO₂ from ice cores

281 We sought to assess if there is evidence for air-sea equilibrium or disequilibrium in the WEP
282 during the large amplitude late Pleistocene glacial/interglacial cycles, in order to validate our
283 approach. We reconstructed pCO₂ for the last 800 kyr (n=16, Fig. 3). For the last 800 kyr,
284 reconstructed pCO₂ values for Sites 806 and 807 are in the range from ice cores (Fig. 3, Petit et al.,
285 1999, Siegenthaler et al., 2005, Lüthi et al., 2008; compilation from Bereiter et al., 2015). The two
286 critical diagnostics we used for method validation are: 1) that the $\delta^{11}\text{B}$ -based reconstruction of pCO₂
287 is consistent with ice core atmospheric CO₂ and 2) the boron-based reconstruction empirically
288 reproduces interglacial-glacial amplitudes from ice cores. Fig. 3B shows that both of these criteria are
289 met. We also created a crossplot comparing these two independent constraints on pCO₂ (Fig. 3C).
290 Two regressions between ice core pCO₂ and boron-based pCO₂ are shown, with a simple linear
291 regression (grey line) and a Deming regression that factors in error in variables (blue line), and
292 bootstraps of outputs shown (n=1000, Figure 3C, Table S6). While slopes and intercepts are not
293 statistically different from a 1:1 line, the regressions do not reach a high significance level (p=0.25);
294 boosting the resolution of the record could help provide better constraints for this type of comparison.
295 The age models for the site do not provide an explanation for this variability based on comparison of
296 the benthic $\delta^{18}\text{O}$ records for both Sites 806 and 807 (Fig. 3A, Zhang et al., 2007; Lear et al., 2003;

297 Lear et al., 2015) to the published isotopic stack (Lisiecki and Raymo, 2004). No significant
298 difference in variability was observed at either site. We also note that reconstructed pCO_2
299 uncertainties (both accuracy and precision) could potentially arise from Mg/Ca-derived estimates of
300 temperature; these uncertainties could be reduced using independent temperature proxies for the WEP
301 such as clumped isotope thermometry (Tripathi et al., 2010; 2014), a technique that is not sensitive to
302 the same sources of error as Mg/Ca thermometry, and therefore is an area planned for future work.
303 Other sources of uncertainty that have a larger effect on pCO_2 calculations are the weight/shell
304 correction, while the TA and seawater boron isotope composition have a minor effect over this time
305 interval.

306 Between MIS 7 and 6, our reconstructions exhibit a decrease in temperature (ΔT) of 1.2 °C,
307 an increase in pH (ΔpH) of 0.08 and a decrease in pCO_2 (ΔpCO_2) of 58 ppm. Between stage 3 and 1,
308 we observed an increase of temperature of 2.0 °C, a decrease of pH of 0.13 and an increase in pCO_2 of
309 76 ppm. We also compare results with recent reconstructions in Figs. S1 and S2 (Sosdian et al., 2018;
310 Rae et al., 2021). These results highlight that we are able to reproduce the range of atmospheric pCO_2
311 in the ice core record, and reproduce the amplitude of changes between transitions, with uncertainties
312 typical for this type of work (Hönisch et al., 2019).

313

314 3.3 Sea surface temperature in the WEP

315 Mg/Ca data are consistent at Site 806 (Wara et al., 2005; Tripathi et al., 2009, 2011; Nathan
316 and Leckie, 2009) and Site 872 (Sosdian et al., 2018) in the WEP. The Mg/Ca in *T. sacculifer* has to
317 date not shown a pH dependency (Gray and Evans, 2019) but Mg/Ca of *G. ruber* does and was
318 therefore corrected from this effect (see supplemental material). Data for both species were corrected
319 from salinity and seawater Mg/Ca changes. Mg/Ca-temperatures for Site 872 was reconstructed using
320 published data and the same framework we use here and are presented in Figure 4. Recalculated
321 values for Site 872 are from *D. altispera*, with an offset applied relative to *T. sacculifer*, and show
322 similar variations to our record for the MCO-MMCT periods (Sosdian et al., 2020). Temperatures
323 from Tex_{86} and $U^{K'}_{37}$ are plotted for comparison but those records are limited to the last 12 and 5 Myrs
324 respectively (Zhang et al., 2014).

325 The Mg/Ca data support high temperatures of 35.2 ± 1.3 °C (2SD, n=11) for the early
326 Miocene until the MMCT, with relatively small (ca. 1°C) change from into the MCO, and larger
327 changes out of the MCO. Similarly warm SST for the MCO were reconstructed in the North Atlantic
328 at Site 608 from Tex_{86} (Super et al., 2018). Despite a gap in our compilation from 11.5 to 9.5 Ma,
329 there is a SST decrease of ~6 °C from the MCO to ~7 Ma where temperatures similar to present day
330 values are observed. A decline in temperature during the MMCT is coincident with the timing of a
331 constriction of the Indonesian Seaway, the pre-closure of the trans-equatorial circulation and
332 subsequent formation of a proto-warm pool (Nathan and Leckie, 2009; Sosdian et al., 2020). From 12

333 to 7 Ma, the Mg/Ca-SST record diverges from Tex₈₆ and U^K₃₇-based reconstructions, with higher
334 temperatures. At the same time, a record for the North Atlantic showed a decrease of ~10 °C from the
335 MCO to ~9 Ma (Super et al., 2018). From 7 Ma to present, the record from multiple proxies – Mg/Ca,
336 Tex₈₆, and U^K₃₇, in the WEP agree.

337

338 3.4 Scenarios of seawater $\delta^{11}\text{B}$ and alkalinity used for pCO₂ reconstructions

339 Figures 5 and 6 show the different histories of seawater $\delta^{11}\text{B}$ and alkalinity used for
340 calculations, respectively. Details of calculations are in the Supplemental methods. Following the
341 approach of Tripathi et al. (2009, 2014) and recent literature (Sosdian et al., 2018; Rae et al., 2021), we
342 explored multiple scenarios for the evolution of seawater boron geochemistry (Fig. 5) and alkalinity
343 for calculations of pCO₂ (Figs. 6, S1 and S2). During the interval overlapping with the ice core record,
344 we observe that the choice of model used does not make a significant difference in reconstructed
345 values. During earlier time intervals, we see there is a greater divergence, reflecting larger
346 uncertainties in seawater $\delta^{11}\text{B}$ and alkalinity further back in Earth history.

347 Prior to 10 Ma and during the early Pliocene (~4.5 to 3.5 Ma), calculations of pCO₂ diverge
348 from published values largely because of the different assumptions each study has used for past
349 seawater $\delta^{11}\text{B}$ (Fig. 5). However, we find that when the uncertainty in reconstructed pH is fully
350 propagated, the differences in reconstructed pH values calculated using each of the $\delta^{11}\text{B}_{\text{seawater}}$ histories
351 is not significantly different (Fig. 5 and 6; see also Hönisch et al., 2019). In contrast to the results
352 from Greenop et al. (2017), the record from Raitzsch and Hönisch, (2013) exhibits substantial
353 variations on shorter timescales. Such variability is a challenge to reconcile with the Li isotope record
354 of Misra and Froelich, (2012), given that Li has a shorter residence time than boron while having
355 similar sources and sinks. For the remainder of this study, we use the $\delta^{11}\text{B}_{\text{seawater}}$ history from Greenop
356 et al. (2017) because it is in good agreement with seawater $\delta^7\text{Li}$ (Misra and Froelich, 2012). The
357 recent calculations of seawater pH (Sosdian et al., 2018; Rae et al., 2021) agree with values from our
358 study when uncertainties are taking into account (Fig. 5).

359 The four alkalinity models used in this study diverge prior to 9 Ma, with a maximum
360 difference at ~13 Ma that is also reflected in reconstructed pCO₂ values (Fig. 6). However, all four
361 models yield pCO₂ estimates that are within error of each other when the full uncertainty is
362 considered. Uncertainty in the evolution of seawater alkalinity and seawater $\delta^{11}\text{B}$ leads to differences
363 in the absolute values of pCO₂ reconstructed (Fig. S2), and a divergence in pCO₂ values reconstructed
364 that is largest in the Miocene. The two scenarios that produce the highest divergence in values are
365 those calculated using constant alkalinity relative to those calculated using values from McCaves et al.
366 (2016), with a maximum difference at 15.0 Ma of up to 250 ppm CO₂, and with the latter model
367 producing lower values (Figs. 6B and 6E). Thus, for the MCO, alkalinity is a critical parameter in
368 calculations of absolute pCO₂ values. For the Miocene and earlier intervals, improved constraints on

369 past secular variations of seawater $\delta^{11}\text{B}$ and alkalinity will yield more accurate reconstructions of
370 pCO_2 .

371 For the remainder of this paper, we use the model of Caves et al. (2016) to estimate alkalinity
372 and $\delta^{11}\text{B}_{\text{seawater}}$ determined by Greenop et al. (2017) (e.g. Fig. 6E). We note that two recent syntheses
373 of boron isotope data have been published and compare our results to these findings (Figs. 8 and S2).
374 Sosdian et al. (2018) reports values that are in line with our results in the Miocene but their study does
375 not replicate results from ice cores. Rae et al. (2021) presents reconstructed values that are higher in
376 the Miocene, due to the utilization of different scenarios of seawater $\delta^{11}\text{B}$ and alkalinity compared to
377 this work.

378

379 3.5 Time intervals

380 3.5.1 Miocene

381 The study of Miocene climate is thought to provide a useful analog for changes associated
382 with global warming and melting of polar ice, in concert with ocean circulation (Holbourn et al.,
383 2013). The Miocene epoch (23-5.3 Ma) is characterized by a warm interval, the Miocene Climate
384 Optimum (~17-14.7 Ma - MCO), and an abrupt cooling during the Middle Miocene Climate
385 Transition (~14-13 Ma - MMCT) that led to the expansion of ice on Antarctica and Greenland.
386 Climate modeling supports a role for decreasing CO_2 in this transition (DeConto and Pollard, 2003).
387 However, reconstructions for the Miocene are still relatively limited (Sosdian et al., 2018; Rae et al.,
388 2021; Raitzsch et al., 2021). Boron isotope and alkenone-based pCO_2 reconstructions support higher
389 pCO_2 during the MCO and a decrease over the MMCT (Sosdian et al. 2018; Stoll et al., 2019),
390 consistent with what was previously inferred from B/Ca (Tripathi et al., 2009, 2011; Sosdian et al.,
391 2020).

392 We applied the same framework we used for calculations at Sites 806 and 807 to published
393 boron isotope data from Site 872 (Sosdian et al., 2018) in order to extend the WEP record to the early
394 Miocene (Figs. 7, 8). The Miocene data between Sites 806 and 872 do not overlap as both are low in
395 resolution, but do show excellent correspondence in their trends in $\delta^{11}\text{B}$ and reconstructed pH. For
396 example, the closest datapoints in time at the two sites are at 15.6 Ma at Site 806 with a $\delta^{11}\text{B} = 14.47 \pm$
397 0.21 ‰ , and at 16.7 Ma at Site 872, with a $\delta^{11}\text{B} = 15.12 \pm 0.25 \text{ ‰}$. The pH values we reconstruct are
398 within error of published estimates from Site 872 (Sosdian et al. 2018, Figs. 7D and 8D). Collectively,
399 these data suggest the early Miocene WEP was characterized by a mixed-layer pH of 8.1 ± 0.1 (2 SD,
400 $n=4$) between 19.4 and 21.8 Ma, which decreased to reach a minimum during the MCO of $7.7 (\pm_{0.14}^{0.11})$.

401 Given the sensitivity in absolute pCO_2 to assumptions about the second carbonate system
402 parameter, a few scenarios were explored for the combined 806/807/872 reconstructed pH values. For
403 all alkalinity scenarios we used, reconstructed pCO_2 shows an increase from the Early Miocene to the
404 MCO, with the highest values in the MCO. Recalculated pCO_2 for Site 872 between 19.4 and 21.8 Ma

405 is 232 ± 92 ppm (2 SD, n=4), lower but within error of the ones presented in Sosdian et al. (2018) and
406 also within error of a constant alkalinity scenario (Fig 8D). The main difference between our
407 calculations and published reconstructions occurs between 19.4 and 21.8 Ma, when the same $\delta^{11}\text{B}$
408 data for Site 872 from Sosdian et al. (2018) recalculated in Rae et al. (2021) yield higher pCO_2 , with
409 an average value of 591 ± 238 ppm (2 SD, n=4) because of the different assumptions used in their
410 calculations. This difference is important because the assumptions from Rae et al. (2021) would imply
411 a relatively high and stable pCO_2 from the early Miocene to MCO (Fig. S2), which would imply a
412 decoupling between pCO_2 and temperature with no pCO_2 change during an interval of decreasing
413 benthic $\delta^{18}\text{O}$. However, our reconstructed pCO_2 increase towards the MCO is in line with the
414 observed benthic $\delta^{18}\text{O}$ decrease and $\delta^{13}\text{C}$ increase and suggest a coupling between temperature and
415 pCO_2 over this period. This highlights the critical need for the use of a common set of assumptions for
416 studies. Assumptions may vary between studies depending of the timescales studied, but a common
417 framework is needed. In addition, further constraints on the second carbonate system parameter and
418 on secular changes in seawater $\delta^{11}\text{B}$ will reduce uncertainties in reconstructed pCO_2 , with improved
419 precision.

420 The highest pCO_2 values we reconstruct are during the MCO (Fig. 6E). For the MCO, our
421 estimates are 511 ± 201 ppm (2 SD, n=3, Table 2). The middle Miocene values we reconstruct are in
422 line with previous studies (Greenop et al., 2014; Sosdian et al., 2018). Published $\delta^{11}\text{B}$ -based
423 reconstructions also support higher pCO_2 for the MCO of ~ 350 -400 ppm (Foster et al., 2012) or 300-
424 500 ppm (Greenop et al., 2014) that was recalculated by Sosdian et al. (2018) to be ~ 470 -630 ppm
425 depending on the model of $\delta^{11}\text{B}_{\text{seawater}}$ chosen. During the MCO relative maxima in pCO_2 , our data
426 support very warm sea surface temperatures in the WEP (35.6 ± 0.6 °C 2SD, n=3; Fig. 8C), that
427 merits further examination in future studies. In fact, the highest temperatures recorded in our samples
428 occur when there is a minimum in the global composite record of $\delta^{18}\text{O}$ of benthic foraminifera
429 (Zachos et al., 2001, 2008; Tripathi and Darby, 2018).

430 At the end of the MMCT, we find evidence for changes in pCO_2 and temperature in the WEP
431 (Fig. 8). From 13.5 to 12.7 Ma, we reconstruct an increase of pH ~ 0.21 and a major decrease of pCO_2
432 of ~ 215 ppm during an interval highlighted by Flower and Kennett, (1996), who observed changes in
433 $\delta^{18}\text{O}$ indicative of rapid East Antarctic Ice Sheet growth and enhanced organic carbon burial with a
434 maximum $\delta^{13}\text{C}$ reached at ~ 13.6 Ma (Shevenell et al., 2004; Holbourn et al., 2007). As discussed in
435 section 3.4 the alkalinity model used for the calculations have an important impact during the
436 Miocene which is likely responsible for the different absolute pCO_2 values over the MCO. In
437 comparison, a scenario of constant alkalinity would lead to a pCO_2 during the MCO of 714 ± 313 ppm
438 (2 SD, n=3) and a decrease of ~ 540 ppm during the MMCT. Both those reconstructions could
439 simulate the large-scale advance and retreat of Antarctic ice with such low pCO_2 values (Gasson et al.,
440 2016). At the same time, we find evidence for decline in SST of 3.4 °C to minimum values of 33.3

441 °C. The synchronous shifts in the $\delta^{13}\text{C}$ and $\delta^{18}\text{O}$ of benthic foraminifera are consistent with increased
442 carbon burial during colder periods, thus feeding back into decreasing atmospheric CO_2 , and
443 supporting the hypothesis that the drawdown of atmospheric CO_2 can in part, be explained by
444 enhanced export of organic carbon (Flower and Kennett, 1993, 1996). However, given the limited
445 sampling of this study, we are only able to resolve a pCO_2 decrease toward the end of the MMCT
446 (~13.5 Ma). The higher resolution $\delta^{11}\text{B}$ - pCO_2 from Site 1092 for the MMCT (Raitzsch et al. 2021)
447 reports eccentricity-scale pCO_2 variability; the authors reported that low pCO_2 during eccentricity
448 maxima was consistent with an increase in weathering due to strengthened monsoonal circulation,
449 which would increase nutrient delivery and supporting higher productivity that in turn would impact
450 carbon drawdown and burial, in line with modeling from Ma et al. (2011).

451 The resolution of our data during the late Miocene is low, with a data gap from 12.5 to 9.2
452 Ma, and another gap between 6.5 and 5 Ma. We note the pCO_2 peak at ~9 Ma observed by Sosdian et
453 al. (2018) is not seen in our record although this is likely due to the low resolution of our dataset.
454 Between 9.5 and 7.1 Ma we find evidence for a decrease in atmospheric CO_2 of 100 ppm associated
455 with a decrease in temperature of 1.3 °C. pCO_2 estimates derived from alkenones for Site 1088
456 (Tanner et al., 2020) do not show the same trend as boron-based reconstructions from the WEP or
457 other regions (Figure 6), which might be due to other controls on the alkenone proxy (Badger et al.,
458 2019). A recent publication from Raitzsch et al. (2021) reports a $\delta^{11}\text{B}$ reconstruction of pCO_2 that is
459 within error of other $\delta^{11}\text{B}$ isotope data from the Southern Ocean (Sosdian et al., 2018), although not
460 for the same period as Tanner et al. (2020). pCO_2 differences between our reconstruction and that of
461 Sosdian et al. (2018) and Raitzsch et al. (2021) (Fig. 8) likely reflect assumptions made for
462 calculations (of $\delta^{11}\text{B}$, TA) and the specific mono-specific calibrations used for each study, as well as
463 potential geographic differences in air-sea pCO_2 . These differences do not invalidate the boron isotope
464 proxy but illustrate the impact that specific seawater parameters and calibrations can have on
465 reconstructed pCO_2 values, as well as potential inferences of air-sea disequilibrium.

466

467 3.5.2 Pliocene

468 Oxygen isotope data from a global benthic foraminiferal stack show that the Pliocene epoch
469 (5.3-2.6 Ma) was initially characterized by warm conditions followed by the intensification of
470 glaciation that occurred in several steps, including during MIS M2 (3.312-3.264 Ma), followed by the
471 Middle Pliocene Warm Period (Lisiecki and Raymo, 2005). The Middle Pliocene Warm Period
472 (mPWP – 3.29-2.97 Ma) is considered a relevant geological analogue for future climate change given
473 ~3°C warmer global temperatures and sea levels that were ~20 m higher than today (Dutton et al.,
474 2015; Haywood et al., 2016), and is a target for model intercomparison projects, for which accurate
475 paleo-atmospheric pCO_2 estimates are critical (Haywood et al., 2016).

476 We calculate high pCO_2 values of 419 ± 119 ppm (2 SD, $n=3$, Table 2) between 4.7 to 4.5 Ma

477 during the Early Pliocene warm interval (Figure 9). The pCO₂ data we report provide a higher data
478 density for the Early Pliocene, and exhibit a trend that is in line with the reconstruction from Rae et al.
479 (2021). Our data support values of 530 ± 110 ppm over the mPWP (2 SD, n = 4), higher than
480 previously published data (Figs. 9, S2 and Table 2), although we acknowledge our low data density
481 may not fully sample variability over this period. The similarity between our reconstructed values and
482 those published for Site 871 in the Indian Ocean (Sosdian et al., 2018) suggests that changes in
483 Indonesian through-flow do not induce substantial changes in air-sea exchange in the WEP.

484 The warmth and local pCO₂ maxima of the mPWP (mid-Pliocene Warm Period) was
485 followed by a strong decrease of temperature in upwelling and high latitude regions during from 3.3-
486 2.7 Ma, coincident with glacial intensification in the Northern Hemisphere. This climate transition
487 was hypothesized to be driven by the closure of the Panama seaway the opening of the high latitudes
488 and subsequent modifications of oceanic circulation (Haug and Tiedemann, 1998). However,
489 modeling from Lunt et al. (2008) supports an additional major role for CO₂ in the glaciation. pCO₂
490 thresholds have been proposed to explain the intensification of Northern Hemisphere Glaciation, with
491 values proposed ranging from 280 ppm (DeConto et al., 2008) to 200 to 400 ppm (Koenig et al.,
492 2011).

493 The pCO₂ concentrations that we calculate indicates a reduction to 350 ppm by 2.7 Ma, ~280
494 ppm by 2.6 Ma, and ~210 ppm by 2.4 Ma, in several steps. These results support roughly a halving of
495 CO₂ values when compared to values of ~530 ppm at 3.3 Ma. These values are consistent with the
496 pCO₂ thresholds proposed by both DeConto et al. (2008) and Koenig et al. (2011) for the
497 intensification of Northern Hemisphere glaciation and the low atmospheric CO₂ (280 ppmv) scenario
498 from Lunt et al. (2008). Mg/Ca SST decline from 30°C to 26°C, supporting an Earth System
499 sensitivity of ~4°C/doubling of CO₂ over this range, although given uncertainties, higher values of
500 ~6°C/doubling of CO₂ that have recently been proposed (Tierney et al., 2020) can not be excluded.

501 We speculate that associated with Pliocene glacial intensification, at 4.42, 3.45 and 2.67 Ma,
502 it is possible that the declines in CO₂ and ice growth in turn drove substantial changes in pole-to-
503 equator temperature gradients and winds, that in turn may have impacted iron cycling (Watson et al.,
504 2000; Robinson et al., 2005; Martinez-Garcia et al., 2011), stratification (Toggweiler, 1999; Sigman et
505 al., 2010), and other feedbacks that impact the amplitude of glacial/interglacial cycles and have been
506 implicated as factors that could have contributed to Pliocene glacial intensification. Specifically, as
507 the mean climate state of the planet became cooler, and glacial-interglacial cycles became larger in
508 amplitude, enhanced windiness and dust transport and upwelling during glacials (Martinez-Boti et al.,
509 2015b) may have enhanced iron fertilization and subsequent carbon export (Martinez-Garcia et al.,
510 2011). While data resolution are limited, we speculate this could explain why glacial/interglacial
511 amplitudes in WEP pCO₂ values decrease from the mPWP towards the Pleistocene, whereas
512 variations in δ¹⁸O are increasing – speculation that could be tested with increased data resolution.

513

514 3.5.3 Pleistocene

515 During the Pleistocene (2.58-0.01 Ma), the climate system experienced a transition in
516 glacial/interglacial (G/I) variability from low amplitude, higher frequency and obliquity-dominated
517 oscillations (i.e., ~ 41 kyr) of the late Pliocene to the high amplitude, lower frequency and
518 eccentricity-dominated cycles (i.e., ~100 kyr) of the last 800 kyr. This transition is termed the Middle
519 Pleistocene Transition (1.2-0.8 Ma – MPT). Questions have been raised about the role of atmospheric
520 CO₂ during this transition, including using boron-based proxies (Hönisch et al., 2009; Tripathi et al.,
521 2011; Chalk et al., 2017). Previous boron isotope studies for ODP Sites 668 and 999 in the tropical
522 Atlantic Ocean have suggested that a decline in atmospheric CO₂ did occur during glacial periods in
523 the MPT, but not during interglacials (Hönisch et al., 2009; Chalk et al., 2017; Dyez et al., 2018).

524 Our pCO₂ concentrations for Sites 806/807 reported here are in good agreement with those
525 determined from ice cores from the early Pleistocene (Yan et al., 2019, Figs. 9 and 10), and with the
526 boron-derived pCO₂ from a recent compilation (Rae et al., 2021). Results for the MPT are broadly in
527 the range of values reported by Hönisch et al. (2009) and Chalk et al. (2017). Although our data are
528 relatively limited, we note they have greater resolution for the middle and later part of the transition
529 than prior publications that have drawn conclusions about the MPT (Hönisch et al., 2009; Chalk et al.,
530 2017; Dyez et al., 2018) (Fig. 10D) and therefore we explore their implications.

531 Taken alone, or when combined with the published data from Chalk et al. (2017) (that is also
532 based on MC-ICPMS), our results support a possible reduction of both glacial and interglacial pCO₂
533 values. We also find evidence that during the MPT, glacial pCO₂ declined rapidly from 189 ±30 ppm
534 at MIS 36 (Chalk et al., 2017) to reach a minimum of 170 (\pm_{24}^{52}) ppm during MIS 30. We note that
535 pCO₂ concentrations are within error when uncertainty is fully propagated, and then remained
536 relatively stable until the end of the MPT whereas interglacial pCO₂ values decrease gradually to
537 reach post-MPT values.

538 In our record for the last 16 Myr, the lowest pCO₂ is recorded at MIS 30 during the MPT,
539 with values of 164 (\pm_{35}^{44}) ppm, which supports an atmospheric CO₂ threshold that leads to large sheet
540 generation. During this transition, the pCO₂ threshold needed to build sufficiently large ice sheets that
541 were able to survive the critical orbital phase of rising obliquity to ultimately switch to a 100 kyr
542 world, was likely reached at MIS 30, but a higher pCO₂ resolution of the MPT is needed for
543 confirmation. The multiple feedbacks resulting from stable ice sheets (iron
544 fertilization/productivity/changes in albedo/ changes in deep water formation) might have sustained
545 larger mean global ice volumes over the subsequent 800 kyr. An asymmetrical decrease between
546 pCO₂ values during interglacials relative to glacials, with glacials exhibiting the largest change across

547 the MPT, would have led to increased sequestration of carbon during glacials in the 100 kyr world, as
548 discussed by Chalk et al. (2017), with increased glacial dust input and iron fertilization.

549

550 3.6 Changes in volcanic activity and silicate weathering, and long-term pCO₂

551 On million-year timescales, atmospheric CO₂ is controlled by its input through mantle
552 degassing in the form of sub-aerial and sub-aqueous volcanic activity and its removal by chemical
553 weathering of continental silicate rocks. Over the last 16 Myr, two relative maxima in atmospheric
554 pCO₂ are observed in our record, one during the MCO (at 15.67 Ma) and a second around the late
555 Miocene/early Pliocene (beginning at 4.7 and 4.5 Ma) (Fig. 11), though the timing for the latter is not
556 precise. The strong pCO₂ increase from the early Miocene to MCO is timely with increasing volcanic
557 activity (Foster et al. 2012), associated with the eruption of the Columbia River Flood Basalts (Hooper
558 et al., 2002; Kasbohm and Schoene, 2018), with recent geochronologic evidence published supporting
559 higher eruption activity between 16.7 and 15.9 Ma (Kasbohm and Schoene, 2018) reinforcing the idea
560 of an episodic pCO₂ increase during the MCO due to volcanic activity. Underestimation of net CO₂
561 outgassing from specific continental flood basalt eruption is possible, as both sub-aqueous and sub-
562 aerial flood basalts, under right climatic conditions, are prone to enhanced chemical weathering. For
563 example, the 4-5‰ drop in δ⁷Li record at the K-Pg boundary (Misra and Froelich, 2012) is attributed
564 to rapid quasi-congruent weathering of Deccan Traps (Rene et al. 2015) during their eruption.
565 Courtillot and Rene (2003) estimate that about 50% of emitted CO₂, roughly equivalent to the amount
566 emitted by the eruption of a million cubic kilometers of Deccan Traps, may be missing due to
567 chemical and physical weathering. Additionally, the early Eocene (at ~50 Ma) 3-4‰ rise in seawater
568 δ⁷Li at a time where there is not significant uplift of the Himalayas (Misra & Froelich, 2012) is also
569 attributed to incongruent weathering of previously erupted Deccan Trap basalts as the Indian
570 subcontinent moved from arid mid-latitudes to the wet low latitudes (Kent and Muttoni, 2008). Thus,
571 a significant part of the outgassed CO₂ can be consumed by chemical weathering of freshly erupted
572 hot basalts (Courtillot et al., 2003). However, the congruency of chemical weathering of basalts,
573 depending on regional climatic conditions (warm-wet vs. cold-arid), will determine the nature of
574 observable inflection in the seawater δ⁷Li. The possible quantification of increased rates of silicate
575 weathering inferred from δ⁷Li (mentioned below) can be utilized to determine total eruptive volume
576 (missing + existing) and volatile emissions from the Columbia River Flood Basalts. At the same time
577 as continental flood basalt emissions, enhanced seafloor production could also be a second possible
578 source of CO₂; however, we note there is evidence that the rate of seafloor production has remained
579 virtually invariant over the last 60 million years (Rowley, 2002; Muller et al. 2016).

580 The second CO₂ peak can possibly be caused either by the observed increase in global
581 volcanism during the early/middle Pliocene (Kennett and Thunell, 1977; Kroenke et al., 1993), and/or
582 a by change in silicate weathering regime. Strontium and lithium isotopes (^{87/86}Sr and δ⁷Li) have been
583 used as proxy for silicate weathering flux and congruency. Although the strontium isotope record

584 exhibits a monotonous increase, lithium isotope data (Misra and Froelich, 2012) are more variable
585 with a transition from a period of increase seawater $\delta^7\text{Li}$ (e.g. non-steady state weathering) to stable
586 seawater $\delta^7\text{Li}$ (e.g., steady state weathering) beginning at roughly 6.8 Ma (Fig. 11).

587 It is interesting to note that the rise in $\delta^7\text{Li}$ (Fig. 11B) from the early Miocene to the MCO are
588 synchronous with the rise in $p\text{CO}_2$. Before 18.5 Ma, the $p\text{CO}_2$ is relatively stable, $\delta^7\text{Li}$ is increasing,
589 suggesting non-steady state / incongruent nature of continental chemical weathering. From 18.6 to
590 16.7 Ma, the $\delta^7\text{Li}$ record decreases by $\sim 2\%$, consistent with decreasing weathering rates and an
591 associated increase in $p\text{CO}_2$. Between 16.7 and 15.9 Ma, when the eruption of the Columbia River
592 Flood Basalts is at a maximum, $\delta^7\text{Li}$ increases, in line with higher weathering rates that could arise
593 from higher atmospheric CO_2 and the presence of fresh basalts. The $\delta^7\text{Li}$ record then decreases again
594 until the end of the MCO at ~ 14.7 Ma, in line with a decrease in the eruption rate, sustaining high
595 atmospheric CO_2 . A constant increase in $\delta^7\text{Li}$ is then observed, until the early Pliocene, where there is
596 evidence for a shift to a steady-state weathering regime. This increase in $\delta^7\text{Li}$ is also consistent with
597 the decrease in $p\text{CO}_2$ observed until the early Pliocene.
598

599 3.9 Conclusions

600 We developed a reconstruction of atmospheric $p\text{CO}_2$ based on $\delta^{11}\text{B}$ of planktic foraminifera
601 from ODP Sites 806 and 807 located in the Western Equatorial Pacific for the past 16 million years
602 and extended the record to 22 Ma by reprocessing data from Site 872 (Sosdian et al., 2018). We build
603 on past efforts to reconstruct atmospheric $p\text{CO}_2$ using different proxies from this region, including
604 from carbon isotopes in marine organic matter (Rayno et al., 1996) and alkenones (Pagani et al.,
605 2010), as well as foraminiferal B/Ca ratios (Tripathi et al., 2009, 2011), all of which have been shown
606 to have a number of complexities and potential sources of systematic error (e.g., Tripathi et al., 2011).
607 It also builds on efforts using boron isotopes in other regions using MC-ICP-MS (Seki et al., 2010;
608 Foster et al., 2012, 2014; Greenop et al., 2014; Martinez-Boti et al., 2015b; Stap et al., 2016; Chalk et
609 al., 2017; Dyez et al., 2018; de la Vega et al., 2020), and our recent work constraining fractionation
610 factors and measuring small samples of foraminifera (Guillermic et al., 2020).

611 Our study contributes a new long-term reconstruction of atmospheric $p\text{CO}_2$ for the Neogene
612 derived from boron isotopes from the tropical Pacific Ocean. Although the record is not continuous,
613 with variable resolution, it captures both long-term and short-term variability associated with several
614 key transitions and demonstrates the utility of examining sites in the Western Equatorial Pacific for
615 future higher-resolution studies. Results for Sites 806 and 807 in the Western Equatorial Pacific
616 reproduce the amplitude of late Pleistocene glacial-interglacial cycles in $p\text{CO}_2$. These observations are
617 consistent with the sites being in equilibrium with the atmosphere, although further work would be
618 useful to explore sources of uncertainty and differences relative to ice core $p\text{CO}_2$.

619 Values increase from the Miocene to the Miocene Climatic Optimum, and the MCO values
620 for this region has higher $p\text{CO}_2$ than reconstructions from other areas, with values estimated as $511 \pm$

621 201 ppm (2 SD, $n=3$). These elevated values are likely linked to the eruption of the Columbia River
622 Flood Basalts, with values declining into the early Pliocene, including during Pliocene glacial
623 intensification. The changes in $p\text{CO}_2$ we observed are in line with changes in $\delta^7\text{Li}$, a proxy of silicate
624 weathering, and future modeling of multiple proxy records should be insightful. Early Pliocene data
625 for $\sim 4.7\text{-}4.5$ Ma support high $p\text{CO}_2$ of 419 ± 119 ppm, and elevated values during the mid-Pliocene
626 Warm Period of 530 ± 110 ppm for $\sim 3.3\text{-}3.0$ Ma. These data are low in resolution, thereby not fully
627 sampling orbital and millennial scale variability. The higher resolution record for Pliocene glacial
628 intensification supports a reduction in $p\text{CO}_2$ during several steps, with values at 2.7 Ma of 350 ppm,
629 2.6 Ma of ~ 280 ppm, and 2.4 Ma of ~ 210 ppm. We find support for a larger reduction in glacial $p\text{CO}_2$
630 during the Mid-Pleistocene Transition compared to interglacial $p\text{CO}_2$, and a minimum in $p\text{CO}_2$ during
631 glacial MIS 30. These findings confirm a role for CO_2 in the transition from a 41 kyr to a 100 kyr
632 world.

633 Higher-resolution boron isotope records from the WEP would allow for further resolution of
634 these changes. Additional constraints on temperature, such as from clumped isotopes (Tripathi et al.,
635 2010) in the WEP (Tripathi et al., 2014), could allow for uncertainties in $p\text{CO}_2$ estimates from boron
636 isotopes to be reduced and for new constraints on Earth climate sensitivity. Future constraints on the
637 vertical structure of the tropical Pacific (Shankle et al., 2021) during these transitions may also
638 potentially be illuminating.

639

640 **Data availability**

641 All data are available in the supplemental materials. Reconstructed climate parameters and proxy data
642 will be archived at the NOAA's NCEI World Data Service for Paleoclimatology on acceptance at
643 <https://www.ncei.noaa.gov/products/paleoclimatology>.

644

645 **Author Contributions**

646 AT developed the project and wrote the proposals that funded the work. All authors contributed to the
647 experimental design. MG performed the measurements with assistance from SM. MG conducted data
648 analysis with input from AT. MG drafted the paper, which was edited by all authors. Interpretation
649 was led by MG and AT, with input from SM and RE.

650

651 **Competing interests**

652 The authors declare that they have no conflict of interest.

653

654 **Acknowledgments**

655 The authors wish to thank the Tripathi Lab, including Lea Bonnin and Alexandra Villa, for assistance
656 with picking samples; the IODP core repository for provision of samples; Mervyn Greaves for

657 technical support and use of laboratory space at the University of Cambridge; Yoan Germain,
658 Emmanuel Ponzevera, Céline Liorzou and Oanez Lebeau for technical support and use of laboratory
659 space at IUEM and Ifremer (Plouzané, France). We thank Thomas Chalk, another anonymous
660 reviewer, and Hubertus Fischer for their helpful comments on the manuscript, and Mathis Hain for
661 discussion of this work.

662

663 **Financial support**

664 This research is supported by DOE BES grant no. DE-FG02-13ER16402 to AKT, by the International
665 Research Chair Program that is funded by the French government (LabexMer ANR-10-LABX-19-01)
666 to AKT and RAE, and IAGC student research grant 2017.

1068 **Figure captions**

1069 **Figure 1:** Modern hydrography of sites. **A.** Map of air-sea pCO₂ ($\Delta p\text{CO}_2$, ppm, data from Takahashi
1070 et al. (2014) and plotted using Ocean Data View from Schlitzer, (2016) showing the location of ODP
1071 Sites 806 and 807 (black circles) and Site 872 (black square, Premoli et al., 1993). Depth profiles are
1072 for preindustrial parameters, **B.** pH calculated from GLODAP database and corrected from
1073 anthropogenic inputs, **C.** Boron isotopic composition of borate ion ($\delta^{11}\text{B}_{\text{borate}}$) with associated
1074 propagated uncertainties.

1075 **Figure 2:** Foraminiferal data for the Miocene to Recent. **A.** Benthic foraminiferal $\delta^{18}\text{O}$ data (blue line
1076 – stack from Lisiecki and Raymo, 2005; black line – compilation from Zachos et al., 2008). **B.** $\delta^{11}\text{B}$ of
1077 *T. sacculifer* (blue circles) and *G. ruber* (blue triangles) at Sites 806 (light blue), 807 (dark blue), Grey
1078 filled square are data from Site 872 located in the WEP (Sosdian et al., 2018). Open symbols are $\delta^{11}\text{B}$
1079 data from published studies (Hönisch and Hemming, 2009; Seki et al., 2010; Foster et al., 2012;
1080 Greenop et al., 2014; Martinez-Boti et al., 2015a; Chalk et al., 2017; Dyez et al., 2018; Sosdian et al.,
1081 2018; de la Vega et al., 2020; Raitzsch et al., 2021), grey open symbols are *T. sacculifer*, brown open
1082 symbols are for *G. ruber*. **C.** Mg/Ca ratios of *T. sacculifer* and *G. ruber* at Sites 806, 807 and fourth-
1083 order polynomial regression from Sosdian et al. (2020) representing secular variations of Mg/Ca_{sw}
1084 (blue dotted line). **E.** Calculated weight per shell for *T. sacculifer* and *G. ruber*. For Panels B-D:
1085 Circles = *T. sacculifer*, Triangles = *G. ruber*.

1086 **Figure 3:** **A.** Reconstruction of surface pCO₂ (ppm) for the past 0.8 Myr from *T. sacculifer* at ODP
1087 Sites 806 and 807 (blue symbols) using boron-based pH calculated from $\delta^{11}\text{B}_{\text{seawater}}$ (Greenop et al.,
1088 2017) and alkalinity from Caves et al. (2016). Planktonic foraminiferal $\delta^{18}\text{O}$ at site 806 with isotope
1089 stages labeled (black line – Medina-Elizalde and Lea, 2005) and benthic foraminiferal $\delta^{18}\text{O}$ stack
1090 (grey line - Lisiecki and Raymo, 2005), benthic $\delta^{18}\text{O}$ at Site 806 (dark red line) from Lear et al. (2003,
1091 2015). **B.** pCO₂ values calculated from boron isotopes (colored symbols - this study) with data from
1092 the literature (open gray triangles – compilation B are data recalculated in Rae et al., 2021) and ice
1093 core pCO₂ (black line – Petit et al., 1999, Lüthi et al., 2008, Bereiter et al., 2015). **C.** Cross plot for the
1094 last 0.8 Myr of pCO_{2T. sacculifer} from this study and pCO_{2_ice core} (from ice core compilation, Bereiter
1095 et al., 2015), grey line is a simple linear regression: $p = 0.25$, $R^2=0.09$, blue line is a Deming
1096 regression with bootstrap (n=1000) taking into account both x and y uncertainties ($p = 0.25$), ice core
1097 CO₂ error calculated based 2 SD on ± 1 ky on the age determined from age model and boron based
1098 pCO₂ error is calculated based on error propagation eq. S17, outputs of the regression are presented in
1099 Table S6. Data compiled are from: Foster et al., 2008; Hönisch and Hemming, 2009; Seki et al., 2010;
1100 Foster et al., 2012; Badger et al., 2013; Greenop et al., 2014; Martinez-Boti et al., 2015a; Chalk et al.,
1101 2017; Dyez et al., 2018; Sosdian et al., 2018; Greenop et al., 2019; de la Vega et al., 2020.

1102 **Figure 4:** Compilation of temperature from site 806 in the WEP. Mg/Ca based temperature were
1103 derived using the same framework (see supplemental information). Blue filled symbols are from Sites
1104 806 and 807 with blue circles for *T. sacculifer* and triangles for *G. ruber*; filled gray squares are data
1105 from Site 872 (Sosdian et al., 2018). Open symbols are SST derived from Mg/Ca at Site 806 (Wara et
1106 al., 2005; Tripathi et al., 2009; Nathan and Leckie, 2009). $\text{Te}_{\text{X}86}$ and U^{K}_{37} are also plotted for
1107 comparison (Zhang et al., 2014). Orange open circles are SST data calculated with our framework
1108 from the species *D. altispera* at ODP Site 806 (Sosdian et al., 2020) with an offset of +8°C. Blue line
1109 is a smooth line (Lowess) going through the data.

1110
1111 **Figure 5:** Different models for the evolution of the boron geochemistry explored as part of this work.
1112 Due to the 1 ‰ uncertainty propagated for $\delta^{11}\text{B}_{\text{seawater}}$, all scenarios yield reconstructed seawater pH
1113 values that are within error of each other. Propagated uncertainties were calculated using eq. S14 (see
1114 Supplement). **A.** Different models for $\delta^{11}\text{B}_{\text{seawater}}$ used for the reconstruction of pCO₂ in this study
1115 (blue – Lemarchand et al., 2000; green – Greenop et al., 2017; red – Raitzsch and Hönisch, 2013). **B.**
1116 Reconstructed pH based on our measured $\delta^{11}\text{B}_{\text{carbonate}}$ values using different models for $\delta^{11}\text{B}_{\text{seawater}}$
1117 (blue – Lemarchand et al., 2000; green – Greenop et al., 2017; red – Raitzsch and Hönisch, 2013),

1118 compilations of pH from Sosdian et al. (2018) (compilation A - open squares) and Rae et al. (2021)
1119 (compilation B - open triangles) are also shown for comparison. Data for compilation A are from:
1120 Hönisch and Hemming, 2009; Seki et al., 2010; Foster et al., 2012; Badger et al., 2013; Greenop et
1121 al., 2014; Martinez-Boti et al., 2015a; Chalk et al., 2017; Sosdian et al., 2018. Data for compilation B
1122 are from: Foster et al., 2008; Hönisch and Hemming, 2009; Seki et al., 2010; Foster et al., 2012;
1123 Badger et al., 2013; Greenop et al., 2014; Martinez-Boti et al., 2015a; Chalk et al., 2017; Dyez et al.,
1124 2018; Sosdian et al., 2018; Greenop et al., 2019; de la Vega et al., 2020.

1125
1126 **Figure 6:** Different models for the evolution of a second carbonate (e.g. alkalinity) system parameter
1127 explored as part of this work. The propagated uncertainties were calculated using eq. S16 (see
1128 Supplement). **A.** Different models for alkalinity used for the reconstruction of pCO₂ in this study
1129 (brown – constant alkalinity of 2330 μmol/kg, blue - Ridgwell and Zeebe, 2005; green - Tyrell and
1130 Zeebe, 2004; violet - Caves et al., 2016. Colored symbols are reconstructed pCO₂ based on our
1131 measured δ¹¹B_{carbonate} values, alkalinity scenario and δ¹¹B_{seawater} from Greenop et al., 2017; open
1132 squares (compilation A) are pCO₂ compilation from Sosdian et al. (2018), open triangles (compilation
1133 B) are from compilation from Rae et al. (2021), black symbols are from site 872. **B.** Reconstructed
1134 pCO₂ using constant alkalinity of 2330 μmol/kg and δ¹¹B_{seawater} from Greenop et al. (2017). **C.**
1135 Reconstructed pCO₂ using constant alkalinity scenario from Ridgwell and Zeebe, (2005) and
1136 δ¹¹B_{seawater} from Greenop et al. (2017). **D.** Reconstructed pCO₂ using constant alkalinity scenario from
1137 Tyrell and Zeebe, (2004) and δ¹¹B_{seawater} from Greenop et al. (2017). **E.** Reconstructed pCO₂ using
1138 constant alkalinity scenario from Caves et al., (2016) and δ¹¹B_{seawater} from Greenop et al. (2017). In
1139 black are published estimates from ice core data (circles - Yan et al., 2019). Compilations of pCO₂
1140 from Sosdian et al. (2018) (compilation A - open squares) and Rae et al. (2021) (compilation B - open
1141 triangles) are also shown for comparison. Data for compilation A are from: Hönisch and Hemming,
1142 2009; Seki et al., 2010; Foster et al., 2012; Badger et al., 2013; Greenop et al., 2014; Martinez-Boti et
1143 al., 2015a; Chalk et al., 2017; Sosdian et al., 2018. Data for compilation B are from: Foster et al.,
1144 2008; Hönisch and Hemming, 2009; Seki et al., 2010; Foster et al., 2012; Badger et al., 2013;
1145 Greenop et al., 2014; Martinez-Boti et al., 2015a; Chalk et al., 2017; Dyez et al., 2018; Sosdian et al.,
1146 2018; Greenop et al., 2019; de la Vega et al., 2020. Stars indicate pCO₂ values reconstructed from
1147 alkenones by Tanner et al. (2020) (simulation 6) at Site 1088 in the Southern Ocean.

1148
1149 **Figure 7:** Proxy data for the past 22 million years in the Western Equatorial Pacific compared to
1150 benthic oxygen isotope data. **A.** Benthic δ¹⁸O (blue line – stack from Lisiecki and Raymo, 2005; black
1151 line – compilation from Zachos et al., 2008). **B.** Benthic δ¹³C (black line – compilation from Zachos et
1152 al., 2008). **C to E,** colored is indicating the site (filled light blue=806, filled dark blue=807), symbols
1153 represent the species (circle=*T. sacculifer* and triangle=*G. ruber*), filled grey squares are recalculated
1154 data based on Sosdian et al. (2018) at site 872. **C.** SST reconstructed at ODP Sites 806 and 807 using
1155 Mg/Ca ratios (see supplemental informations for reconstruction details), open symbols are
1156 reconstructed temperature based on literature Mg/Ca at site 806 (see text or Fig. 4). **D.** Seawater pH
1157 reconstructed from δ¹¹B of *T. sacculifer* and *G. ruber* using δ¹¹B_{seawater} from Greenop et al. (2017)
1158 (refer to text and supplement for calculations, this study), open squares (compilation A) are
1159 compilation data from Sosdian et al. (2018) and open triangles (compilation B) are compilation from
1160 Rae et al. (2021). **E.** Reconstructed pCO₂ (ppm) using boron-based pH and alkalinity from Caves et al.
1161 (2016), data presented are from this study. Propagated uncertainties are given by eq. S17 for the dark
1162 blue envelope, while the light blue envelope are the uncertainties calculated based on eq. S16 (taking
1163 into account uncertainty on δ¹¹B_{seawater}). Crosses are original pCO₂ calculated in Sosdian et al. (2018)
1164 at Site 872; asterisks are recalculated pCO₂ at Site 872 by Rae et al. (2021).

1165 **Figure 8:** Proxy data from 22 to 6 million years, including the Middle Miocene Climate Transition
1166 (MMCT) and Miocene Climate Optimum (MCO), in the Western Equatorial Pacific compared to
1167 benthic oxygen isotope data. **A.** Benthic δ¹⁸O (black line – compilation from Zachos et al., 2008). **B.**
1168 Benthic δ¹³C (black line – compilation from Zachos et al., 2008). **C and D,** colored is indicating the
1169 site (filled light blue=806, filled dark blue=807), symbols represent the species (circle=*T. sacculifer*

1170 and triangle=*G. ruber*), filled grey squares are recalculated data based on Sosdian et al. (2018) at site
1171 872. **C.** SST reconstructed at ODP Sites 806 and 807 using Mg/Ca ratios (see supplemental
1172 informations for reconstruction details), open symbols are reconstructed temperature based on
1173 literature Mg/Ca at site 806 (see text or Fig. 4). **D.** Reconstructed pCO₂ (ppm) from this study (blue
1174 symbols) using boron-based pH and alkalinity from Caves et al. (2016). Propagated uncertainties are
1175 given by eq. S17 for the dark blue envelope, while the light blue envelope reflects the uncertainties
1176 calculated based on eq. S16 (taking into account uncertainty on $\delta^{11}\text{B}_{\text{seawater}}$). Orange datapoints and
1177 envelope are calculated pCO₂ and associated uncertainty from our study using our framework and a
1178 constant alkalinity scenario. Open squares (compilation A) are compilation data from Sosdian et al.
1179 (2018), open triangles are data from Raitzsch et al. (2021) at Site 1092. Crosses are original pCO₂
1180 calculated in Sosdian et al. (2018) at Site 872; asterisks are recalculated pCO₂ at Site 872 by Rae et al.
1181 (2021); dark red triangles are from Site 1092 (Raitzsch et al., 2021). Data for compilation A are from:
1182 Hönisch and Hemming, 2009; Seki et al., 2010; Foster et al., 2012; Badger et al., 2013; Greenop et
1183 al., 2014; Martinez-Boti et al., 2015a; Chalk et al., 2017; Sosdian et al., 2018. Data for compilation B
1184 are from: Foster et al., 2008; Hönisch and Hemming, 2009; Seki et al., 2010; Foster et al., 2012;
1185 Badger et al., 2013; Greenop et al., 2014; Martinez-Boti et al., 2015a; Chalk et al., 2017; Dyez et al.,
1186 2018; Sosdian et al., 2018; Greenop et al., 2019; de la Vega et al., 2020.

1187 **Figure 9:** Proxy data from 7 to 1 million years, including the Warm Pliocene Transition (WPT), in the
1188 Western Equatorial Pacific compared to benthic oxygen isotope data. **A.** Benthic $\delta^{18}\text{O}$ (black line –
1189 compilation from Zachos et al., 2008). **B.** Benthic $\delta^{13}\text{C}$ (black line – compilation from Zachos et al.,
1190 2008). **C and D,** colored is indicating the site (filled light blue=806, filled dark blue=807), symbols
1191 represent the species (circle=*T. sacculifer* and triangle=*G. ruber*), filled grey squares are recalculated
1192 data based on Sosdian et al. (2018) at ODP Site 872. **C.** SST reconstructed at ODP Sites 806 and 807
1193 using Mg/Ca ratios (see supplemental informations for reconstruction details), open symbols are
1194 reconstructed temperature based on literature Mg/Ca at site 806 (see text or Fig. 4). **D.** Reconstructed
1195 pCO₂ (ppm) from this study (blue symbols) using boron-based pH and alkalinity from Caves et al.
1196 (2016). Propagated uncertainties are given by eq. S17 for the dark blue envelope, while the light blue
1197 envelope reflects the uncertainties calculated based on eq. S16 (taking into account uncertainty on
1198 $\delta^{11}\text{B}_{\text{seawater}}$). Open squares (compilation A) are pCO₂ compilation from Sosdian et al. (2018), open
1199 triangles (compilation B) are from compilation from Rae et al. (2021). Data for compilation A are
1200 from: Hönisch and Hemming, 2009; Seki et al., 2010; Foster et al., 2012; Badger et al., 2013;
1201 Greenop et al., 2014; Martinez-Boti et al., 2015a; Chalk et al., 2017; Sosdian et al., 2018. Data for
1202 compilation B are from: Foster et al., 2008; Hönisch and Hemming, 2009; Seki et al., 2010; Foster et
1203 al., 2012; Badger et al., 2013; Greenop et al., 2014; Martinez-Boti et al., 2015a; Chalk et al., 2017;
1204 Dyez et al., 2018; Sosdian et al., 2018; Greenop et al., 2019; de la Vega et al., 2020. In black are
1205 published estimates from ice core data (circles - Yan et al., 2019).

1206 **Figure 10:** Proxy data from 1.5 to 0.5 million years, including the Middle Pleistocene Transition
1207 (MPT), in the Western Equatorial Pacific compared to benthic oxygen isotope data. **A.** Benthic $\delta^{18}\text{O}$
1208 (blue line – stack from Lisiecki and Raymo, 2005). **B.** Benthic $\delta^{13}\text{C}$ (black line – compilation from
1209 Zachos et al., 2008). **C and D** colored is indicating the site (filled light blue=806, filled dark
1210 blue=807), symbols represent the species (circle=*T. sacculifer* and triangle=*G. ruber*), filled grey
1211 squares (compilation A) are recalculated data based on Sosdian et al. (2018) at site 872. **C.** SST
1212 reconstructed at ODP Sites 806 and 807 using Mg/Ca ratios (see supplemental informations for
1213 reconstruction details), open symbols are reconstructed temperature based on literature Mg/Ca at site
1214 806 (see text or Fig. 4). **D.** Reconstructed pCO₂ (ppm) from this study (blue symbols) using boron-
1215 based pH and alkalinity from Caves et al. (2016). Propagated uncertainties are given by eq. S17. In
1216 black are published estimates from ice core data (line – Bereiter et al., 2015; black circles - Yan et al.,
1217 2019). Open triangles (compilation B) are from compilation from Rae et al. (2021). Data for
1218 compilation B are from: Foster et al., 2008; Hönisch and Hemming, 2009; Seki et al., 2010; Foster et
1219 al., 2012; Badger et al., 2013; Greenop et al., 2014; Martinez-Boti et al., 2015a; Chalk et al., 2017;
1220 Dyez et al., 2018; Sosdian et al., 2018; Greenop et al., 2019; de la Vega et al., 2020.

1221
1222 **Figure 11:** Proxy data from 1.5 to 0.5 million years, including the Middle Pleistocene Transition
1223 (MPT), in the Western Equatorial Pacific compared to benthic oxygen isotope composites. **A.** Benthic
1224 $\delta^{18}\text{O}$ (blue line – compilation from Lisiecki and Raymo, 2005, black line – compilation from Zachos
1225 et al. 2008). **B.** Records from Lithium isotopes ($\delta^7\text{Li}$, orange, Misra and Froelich, 2012) and
1226 Strontium isotopes ($^{87/86}\text{Sr}$, grey, Hodell et al., 1991, Farrel et al., 1995, Martin et al., 1999, Martin et
1227 al., 2004), both proxies for silicate weathering. Orange arrows represent the different weathering
1228 regimes as indicated by the $\delta^7\text{Li}$, black crosses are indication when changes in weathering regime
1229 occurs. **C.** Reconstructed pCO_2 (ppm) using boron-based pH and alkalinity from Caves et al. (2016),
1230 colored is indicating the site (filled light blue=806, filled dark blue=807), symbols represent the
1231 species (circle=*T. sacculifer* and triangle=*G. ruber*), filled grey squares (compilation A) are
1232 recalculated data based on Sosdian et al. (2018) at site 872. Data for compilation A are from: Hönisch
1233 and Hemming, 2009; Seki et al., 2010; Foster et al., 2012; Badger et al., 2013; Greenop et al., 2014;
1234 Martinez-Boti et al., 2015a; Chalk et al., 2017; Sosdian et al., 2018. Propagated uncertainties are
1235 given by eq. S17 for the dark blue envelope, while the light blue envelope are the uncertainties
1236 calculated based on eq. S16 (taking into account uncertainty on $\delta^{11}\text{B}_{\text{seawater}}$). Also shown are timing of
1237 major events. The rose band and dark rose band indicate eruption of the Columbia River flood basalts
1238 (Hooper et al., 2002) and time of maximum eruption (Kasbohm and Schoene, 2018), respectively.
