19 **ABSTRACT**

20 Constraints on the evolution of atmospheric CO₂ levels throughout Earth's history are foundational to our
21 understanding of past variations in climate. Despite considerable effort, records vary in their temporal
22 and spatial coverage and estimates of past CO₂ levels do not always converge, and therefore new records
23 and proxies are valuable. Here we reconstruct atmospheric CO₂ values across major climate transitions
24 over the past 16 million years using the boron isotopic composition ($\delta^{11}\text{B}$) of planktic foraminifera from
25 89 samples obtained from two sites in the West Pacific Warm Pool, Ocean Drilling Program (ODP) Sites
26 806 and 807 measured using high-precision multi-collector inductively-coupled plasma mass
27 spectrometry. We compare our results to published data from Pacific Site 872, also in the Western
28 Equatorial Pacific, that goes back to 22 million years ago. These sites are in a region that today is near
29 equilibrium with the atmosphere and are thought to have been in equilibrium with the atmosphere for the
30 interval studied. We show that data from this region is consistent with ice core data and other boron-based
31 studies. The data show evidence for elevated pCO₂ during the Middle Miocene and Early to Middle
32 Pliocene, and reductions in pCO₂ of ~200 ppm during the Middle Miocene Climate Transition, ~250 ppm
33 during Pliocene Glacial Intensification, and ~50 ppm during the Mid-Pleistocene Climate Transition.
34 There is possible evidence for a larger reduction in glacial pCO₂ during the Mid-Pleistocene Transition
35 compared to interglacial pCO₂, and a minimum in pCO₂ during glacial MIS 30. Our results are consistent
36 with a coupling between pCO₂, temperature and ice sheet expansion from the Miocene to Recent.

37

38 **Highlights**

39 In this study, we reconstruct atmospheric pCO₂ using $\delta^{11}\text{B}$ data from ODP Sites 806 and 807 and compare
40 them with ice core data, demonstrating the fidelity of our approach. We therefore apply the same
41 framework to older samples to create a long-term pH and pCO₂ reconstruction for the past 16 million
42 years, and recalculate pCO₂ for ODP Site 872 from 17 to 22 million years ago. We find major increases
43 in surface water pH and decreases in atmospheric pCO₂ were associated with decreased temperature in
44 the Western Equatorial Pacific, including associated with major episodes of ice sheet expansion in the
45 high latitudes, providing more robust quantitative constraints on the past coupling between pCO₂,
46 temperature, and cryosphere stability.

50 **1. Introduction**

51 Due to concerns about the long-term consequences of anthropogenic emissions and associated
52 climate change (IPCC, 2014, 2018), efforts have been made to quantify past atmospheric CO₂ and
53 examine past relationships between CO₂ and temperature. Such data are not only critical for constraining
54 Earth-system sensitivity (Lea, 2004; Lunt et al., 2010; Pagani et al., 2010; Hansen et al., 2012, 2013,
55 Foster and Rohling, 2013; Schmittner et al., 2011; Tierney et al., 2020), but are also of broad interest
56 because such data can help us understand the evolution of climate and geological systems through Earth's
57 history (Tripathi et al., 2011; Foster et al., 2017; Tripathi and Darby, 2018). However, discrepancies between
58 proxy reconstructions still exist, including for major climate transitions of the Cenozoic. In particular,
59 there remains a pressing need for robust and higher-resolution atmospheric CO₂ records from sites that
60 are in equilibrium with the atmosphere.

61 High-resolution and direct determinations of atmospheric CO₂ are available for the last 800 kyr
62 through analysis of air bubbles extracted from ice-cores, but these records are limited to the availability
63 of cores (Petit et al., 1999; Siegenthaler et al., 2005; Lüthi et al., 2008; Bereiter et al., 2015). A window
64 into atmospheric CO₂ levels comes from 1 million-year-old blue ice (Higgins et al., 2015) and more
65 recently a snapshot from the early Pleistocene period (Yan et al., 2019). Most reconstructions of CO₂ for
66 prior to 800 ka are based on indirect terrestrial and marine proxies. Stomata indices for fossil leaves (Van
67 der Burgh, 1993; Royer, 2001), carbon isotope ratios ($\delta^{13}\text{C}$) of paleosols (Retallak et al., 2009), $\delta^{13}\text{C}$ of
68 alkenones (Pagani et al., 2005; Zhang et al., 2013), B/Ca ratios of surface-dwelling foraminifera (Yu and
69 Hönisch, 2007; Foster, 2008; Tripathi et al., 2009, 2011), and boron isotope ratios ($\delta^{11}\text{B}$) of surface-
70 dwelling foraminifera (Pearson and Palmer, 2000; Hönisch et al., 2009; Bartoli et al., 2011; Foster, 2008,
71 2012; Foster and Sexton, 2014; Chalk et al., 2017; Sosdian et al., 2018; Dyez et al., 2018) have been used
72 to estimate atmospheric CO₂.

73 Each of the above proxy methods has sources of systematic errors that we do not attempt to
74 exhaustively document as they have been discussed in-depth elsewhere (e.g., Pagani et al., 2005; Tripathi
75 et al., 2011; Guillermic et al., 2020). However, we note that significant developments in the boron-based
76 proxies include improvements to the accuracy and precision of measurements using multi-collector
77 inductively coupled mass spectrometry (MC-ICP-MS) compared to early work with thermal ionization

78 mass spectrometry (TIMS), where there were large instrumental mass fractionations and challenges with
79 laboratory intercomparison (Foster et al., 2013; Farmer et al., 2016; Aggarwal and You, 2017). There was
80 also the realization that temperature-dependent K_D to interpreting B/Ca sensitivities observed from the
81 field of sediment trap, core-top, and downcore studies (Yu and Hönisch, 2007; Foster et al., 2008; Tripathi
82 et al., 2009, 2011; Babila et al., 2010; Osborne et al., 2020) differ from foraminiferal culture experiments
83 (Allen et al., 2011, 2012) and inorganic calcite (Mavromatis et al., 2015); this type of discrepancy has
84 also been observed with other elemental proxies (e.g., Mg/Ca). Such differences may be due to differences
85 in growth rates (Sadekov et al., 2014), ontogenetic changes, a correlation in the field between temperature
86 and other hydrographic variables that obscure robust statistical determination of parameter relationships,
87 culture conditions resulting in organisms being stressed, and/or other factors.

88 The marine CO_2 proxy that appears to be subject to the fewest systematic uncertainties, based on
89 our current understanding, is the boron isotopic composition ($\delta^{11}\text{B}$) of planktic foraminifera as measured
90 using MC-ICPMS and TE-NTIMS (Hain et al., 2018). This proxy provides constraints on seawater pH,
91 if temperature, salinity, seawater $\delta^{11}\text{B}$, and the appropriate mono-specific calibration between $\delta^{11}\text{B}_{\text{carbonate}}$
92 and $\delta^{11}\text{B}_{\text{borate}}$ are constrained (Pearson and Palmer, 2000; Foster et al., 2008; Sosdian et al., 2018; Raitzsch
93 et al., 2018; Guillermic et al., 2020). Seawater pH can be used to calculate seawater $p\text{CO}_2$ if there are
94 constraints on a second parameter of the carbonate system (e.g. alkalinity, DIC). Atmospheric $p\text{CO}_2$ can
95 then be constrained if the site being examined is in air-sea CO_2 equilibrium.

96 Given the evolution of the field, there are relatively few studies generating high-precision boron-
97 based records over major climate transitions in the Cenozoic using recent analytical methods, that
98 incorporate our current understanding of the proxy (e.g., Greenop et al., 2014; Martinez-Boti et al., 2015b;
99 Chalk et al., 2017; Dyez et al., 2018; de la Vega et al., 2020). Furthermore, of the existing studies using
100 boron-based proxies, an additional uncertainty frequently exists, namely the short time interval of study
101 (e.g., emphasizing on a climate transition) (Martinez-Boti et al., 2015b; Chalk et al., 2017) and whether
102 the study sites remain in air-sea CO_2 equilibrium with the atmosphere (Martinez et al., 2015a). And
103 although estimation of atmospheric $p\text{CO}_2$ from seawater pH using this proxy is relatively straightforward,
104 reconstructions are still impacted by uncertainties including the lack of robust constraints on a second

105 parameter of the carbonate system, and our limited understanding of secular variations in the $\delta^{11}\text{B}$ of
106 seawater (Tripathi et al., 2011; Greenop et al., 2017; Sosdian et al., 2018; Rae et al., 2021).

107 Therefore, to provide additional constraints on the evolution of atmospheric $p\text{CO}_2$ from the
108 Miocene through Pleistocene, we developed new records from the western tropical Pacific. We use
109 foraminiferal $\delta^{11}\text{B}$ and trace elements in the planktic foraminiferal species *Trilobus sacculifer* and
110 *Globigerinoides ruber* to reconstruct past seawater pH and atmospheric CO_2 at Ocean Drilling Program
111 (ODP) Sites 806 and 807 in the Western Equatorial Pacific (WEP) over the last 16 million years (Myr).
112 The sites are located on the western border of the tropical Pacific Ocean, the largest open-oceanic region
113 on the globe, and the warmest open ocean region at present.

114 These two sites have been examined in other boron-based studies (Wara et al., 2003; Tripathi et al.,
115 2009, 2011; Shankle et al., 2020), as has the region more broadly (Pearson and Palmer, 2000), because it
116 is understood to be in equilibrium with the atmosphere and have relative stable hydrography. The region
117 experiences equatorial divergence but is not strongly affected by upwelling and has a current estimated
118 annual air-sea CO_2 flux of +28 ppmv (Takahashi et al., 2014). The pre-industrial air-sea CO_2 flux is
119 calculated to be +16 ppm, (GLODAP database corrected from anthropogenic inputs), with a value of 298
120 ppm, compared to the Vostok ice core value of 282 ppm at 1.08 ka . This $p\text{CO}_2$ difference is similar to
121 our $p\text{CO}_2$ uncertainty (an average of ~ 17 ppm for the youngest samples). If trade winds were much
122 stronger, and equatorial divergence greater, than this could drive some disequilibrium in the past.
123 However, a few lines of evidence suggest the region was in quasi-equilibrium in the past: 1) zonal
124 temperatures are at a maximum in pre-industrial times and during the Pleistocene, and we are able to
125 reconstruct atmospheric $p\text{CO}_2$ values from the ice cores, 2) temperature proxies indicate the region is
126 relatively stable with respect to temperature compared to other parts of the ocean, and also indicate a
127 weak and stable zonal temperature gradient during the Miocene and Pliocene which would support air-
128 sea stable conditions and air-sea equilibrium (e.g., Nathan and Leckie, 2009; Zhang et al. 2014; Liu et al.,
129 2019).

130 This study builds on low-resolution prior reconstructions for these sites (Wara et al., 2003; Tripathi
131 et al., 2009, 2011; Shankle et al., 2020), Site 872 in the tropical Pacific (Sosdian et al., 2018), and other
132 published boron isotope work, to provide additional data to constrain past seawater pH and $p\text{CO}_2$ for the

133 WEP using MC-ICP-MS, thereby providing an invaluable new perspective on reconstructing past
134 atmospheric CO₂ via marine sediment archives. We explore various constraints on the second carbonate
135 system parameter using a number of different scenarios, following on the systematic work done by Tripathi
136 et al. (2009) and (2011) for B/Ca. We interpret these data using recent constraints on seawater $\delta^{11}\text{B}$
137 (Lemarchand et al., 2000; Raitzsch and Hönisch, 2013; Greenop et al., 2017). For temperature estimation,
138 we utilize a multi-variable model for Mg/Ca (Gray and Evans, 2019), that builds on prior work with
139 clumped isotopes in planktic foraminifera for Site 806 and other WEP sites demonstrating that for the
140 Last Glacial Maximum to recent, salinity-corrected Mg/Ca values are needed to yield convergent
141 estimates of mixed-layer temperatures (Tripathi et al., 2014).

142

143 **2. Materials and Methods**

144 Below we describe site locations, analytical methods used, and figures of merit. The supplemental
145 methods section describes screening for potential contamination, equations used for calculations, and
146 error propagation.

147

148 **2.1 Site locations**

149 Samples are from three ODP holes recovered during Leg 130 in the WEP (Fig. 1, Table 1): Hole
150 806A (0°19.140'N, 159°21.660'E, 2520.7 m water depth), Hole 806B (0°19.110'N, 159°21.660'E, 2519.9
151 m water depth), and Hole 807A (3°36.420'N, 156°37.500'E, 2803.8 m water depth) (Berger et al., 1993).
152 Sites 806 and 807 are not likely to have experienced major tectonic changes over the last 20 million years.

153

154 **2.2 Preservation**

155 Microfossils in sediments at these sites, as with any sedimentary sequences, have the potential to
156 be influenced by diagenesis. Despite evidence of authigenic carbonate formation, recent modeling work
157 concluded the influence of dissolution and reprecipitation at Sites 806 and 807 was relatively minor
158 (Mitnik et al., 2018). Prior work has also found minimal impacts on the B/Ca ratio of Pliocene
159 foraminifera from Site 806 (White and Ravelo, 2020), and on the Mg/Ca ratio of Miocene *D. altispera*
160 shells at Site 806 (Sosdian et al., 2020). The weight/shell ratio is commonly used to monitor dissolution,

161 and the only published record at Site 806 for the Pliocene does not show a trend consistent with dissolution
162 of *T. sacculifer* (Wara et al., 2005). We do note that while the “coccolith size-free dissolution” index
163 reported in Si and Rosenthal (2019) indicates higher dissolution rates in the Miocene, their records were
164 thought to be biased from changes in foraminifera assemblages as discussed in White and Ravelo (2020).

165 To further assess the potential impact of dissolution in our geochemical data, the weight/shell ratio
166 was examined in our samples. The weight/shell data used to monitor dissolution does not exhibit any
167 trend within the interval studied consistent with dissolution. Absolute weights/shell are increasing in the
168 Miocene, which is not consistent with dissolution influencing the record (Fig. 2E). Additionally,
169 reconstructed pH and pCO₂ values also exhibit reasonable correspondence with the Vostok ice core data.
170 Downcore δ¹¹B values from Sites 806 and 807 are similar, despite evidence for higher authigenic
171 carbonate at Site 807 relative to Site 806 (Mitnik et al., 2018). Further, the consistency of our boron
172 isotope and Mg/Ca results with at the two sites with each other, and to the published data from Site 872
173 (Sosdian et al., 2018), each with different sedimentation rates, are not consistent with diagenesis being a
174 primary driver of the record. Comparison of raw data, and derived parameters, is shown in Figs. 2 and 7.

175

176 **2.3 Age models**

177 The age model for Site 806 from 0-1.35 Ma is based on Medina-Elizalde and Lea (2005);
178 calculated ages correspond well with ages from the Lisiecki and Raymo LR04 stack (Fig. 2A). The fourth
179 polynomial regression-based biostratigraphy from Lear et al. (2015) was used for the rest of the record,
180 following other work (Sosdian et al., 2020). Ages for Site 807 are based on published biostratigraphy
181 (Berger et al., 1993) for 807 with additional constraints placed by Zhang et al., (2007) for the interval
182 from 0-0.55 Ma.

183

184 **2.4 Species and trace element cleaning**

185 Samples were picked and cleaned to remove clays at UCLA (Los Angeles, CA) and the University
186 of Western Brittany (Plouzané, France). 50-100 foraminifera shells were picked from the 300-400µm
187 fraction size for *T. sacculifer* (w/o sacc) and from the 250-300 µm for *G. ruber* (white sensu stricto).
188 Picked foraminifera were gently crushed, clays removed, and checked for coarse-grained silicates.

189 Samples were then cleaned using a full reductive and oxidative cleaning protocol following Barker et al.
190 (2003). A final leach step with 0.001N HCl was done prior dissolution in 1N HCl. Boron purification
191 used a published microdistillation protocol (see Misra et al., 2014b, Guillermic et al., 2020 for more
192 detailed methods).

193 194 **2.5 Chemical purification and geochemical analysis**

195 Chemical separation was performed in a boron-free clean lab at the University of Cambridge
196 (Cambridge, UK). Calcium concentrations were measured on an ICP-AES ®Ultima 2 HORIBA at the
197 Pôle Spectrometrie Océan (PSO), UMR6538 (Plouzané, France). Elemental ratios (e.g. X/Ca ratios) were
198 analyzed on a Thermo Scientific ®Element XR HR-ICP-MS at the PSO, Ifremer (Plouzané, France).
199 Boron isotopic measurements were carried out on a Thermo Scientific ®Neptune+ MC-ICP-MS equipped
200 with 10¹³ Ohm resistor amplifiers (Lloyd et al., 2018) at the University of Cambridge (Cambridge, UK).

201 202 **2.6 Standards**

203 Variations in B isotope ratios are expressed in conventional delta (δ) notation with δ¹¹B values
204 reported against the reference standard NIST SRM 951 (NIST, Gaithersburg, MD, USA):

$$205 \quad \delta^{11}\text{B} (\text{‰}) = 1000 \times \left(\frac{{}^{11}\text{B}/{}^{10}\text{B}_{\text{Sample}}}{{}^{11}\text{B}/{}^{10}\text{B}_{\text{NIST SRM 951}}} - 1 \right) \quad \text{eq. 1}$$

206 Multiple analyses of external standards were performed to ensure data quality. For boron isotopic
207 measurements, JC_P-1 (Geological Survey of Japan, Tsukuba, Japan, Gutjahr et al., 2020) was used as a
208 carbonate standard, and NEP, a *Porites sp* coral from University of Western Australia and Australian
209 National University was also used (McCulloch et al., 2014). A boron isotope liquid standard, ERM[®]
210 AE121 (certified δ¹¹B = 19.9 ± 0.6 ‰, SD), was used to monitor reproducibility and drift during each
211 session (Vogl and Rosner, 2012; Foster et al., 2013; Misra et al., 2014b). For trace elements, external
212 reproducibility was determined using the consistency standard Cam-Wuellerstorfi (University of
213 Cambridge) (Misra et al., 2014b).

214

215 **2.7 Figures of Merit**

216 **2.7.1 $\delta^{11}\text{B}$ analyses**

217 Samples measured for boron isotopes typically ranged in concentration from 10 ppb B (~5ng B)
218 to 20 ppb B samples (~10ng B). Sensitivity was 10mV/ppb B (eg. 100mV for 10ppb B) in wet plasma at
219 50 $\mu\text{l}/\text{min}$ sample aspiration rate. The intensity of ^{11}B for a sample at 10 ppb B was typically 104 ± 15 mV
220 (2 SD, typical session) and closely matched the 98 ± 6 mV (2 SD, typical session) of the standard.
221 Procedural boron blanks ranged from 15 pg B to 65 pg B (contributed to less than 1% of the sample
222 signal). The acid blank during analyses was measured at ≤ 1 mV on the ^{11}B (which also is $< 1\%$ of the
223 sample intensity), and no memory effect was seen within and across sessions.

224 External reproducibility was determined by analyzing the international standard JCP-1 (Gutjahr et
225 al., 2020) and a *Porites sp.* coral (NEP). The boron isotopic composition of JCP-1 was measured at 24.06
226 $\pm 0.20\text{‰}$ (2 SD, n=6) within error of published values of $24.37 \pm 0.32\text{‰}$, $24.11 \pm 0.43\text{‰}$ and $24.42 \pm$
227 0.28‰ from Holcomb et al. (2015), Farmer et al. (2016) and Sutton et al. (2018), respectively. Average
228 values are $\delta^{11}\text{B}_{\text{NEP}} = 25.72 \pm 0.79\text{‰}$ (2 SD, n=31) determined over 13 different analytical sessions, with
229 each number representing a separately processed sample from this study. These results are within error
230 of published values of $26.20 \pm 0.88\text{‰}$ (2 SD, n = 27) and $25.80 \pm 0.89\text{‰}$ (2 SD, n = 6), from Holcomb et
231 al. (2015) and Sutton et al. (2018), respectively. Data are reported in Supplementary Table B.

232

233 **2.7.2 X/Ca analyses**

234 Trace element (TE) analyses were conducted at a Ca concentration of either 10 or 30 ppm. Typical
235 blanks for a 30 ppm Ca session were: $^7\text{Li} < 2\%$, $^{11}\text{B} < 7\%$, $^{25}\text{Mg} < 0.2\%$ and $^{43}\text{Ca} < 0.02\%$. Additionally,
236 blanks for a 10 ppm Ca session were: $^7\text{Li} < 2.5\%$, $^{11}\text{B} < 10\%$, $^{25}\text{Mg} < 0.4\%$ and $^{43}\text{Ca} < 0.05\%$. Analytical
237 uncertainty of a single measurement was calculated from the reproducibility of the CamWuellesstorfi
238 standard: $0.6 \mu\text{mol}/\text{mol}$ for Li/Ca, $8 \mu\text{mol}/\text{mol}$ for B/Ca and $0.02 \text{mmol}/\text{mol}$ for Mg/Ca (2 SD, n=48).
239 Data are reported in Supplementary Table B.

240

241 **2.8 Calculations**

242 Detailed calculations can be found in the supplemental materials. Briefly, Mg/Ca was used to
243 reconstruct sea surface temperature (SST) using the framework from Gray and Evans. (2019) correcting
244 for influences of pH and salinity. $\delta^{11}\text{B}_{\text{carbonate}}$ was corrected using an empirical $\delta^{11}\text{B}_{\text{carbonate-weight/shell}}$
245 ratio relationship. $\delta^{11}\text{B}_{\text{borate}}$ was determined using species dependent sensitivities of $\delta^{11}\text{B}_{\text{carbonate}}$ to $\delta^{11}\text{B}_{\text{borate}}$
246 (Guillermic et al., 2020). pH was calculated using the $\delta^{11}\text{B}_{\text{borate}}$ with different scenarios of secular seawater
247 $\delta^{11}\text{B}$ changes (Lemarchand et al., 2002; Raitzsch and Hönisch, 2013; Greenop et al., 2017). pCO_2 was
248 reconstructed using pH based $\delta^{11}\text{B}_{\text{carbonate}}$ and different scenarios of Alkalinity (Tyrell and Zeebe, 2004;
249 Ridgwell and Zeebe, 2005; Caves et al. 2016 and Rae et al. 2021). Further details including equations are
250 in the Supplement.

252 **3. Results and discussion**

253 **3.1 Geochemical results**

254 Geochemical data used in this study are presented in Figure 2. Mg/Ca data (Fig. 2C) are consistent
255 with previously published Mg/Ca values for Site 806 on *T. sacculifer* (Wara et al., 2005; Tripathi et al.,
256 2009; Nathan and Leckie, 2009). Although the record we generated does not overlap with Site 872, they
257 are time-adjacent, and there is a good correspondence with our Mg/Ca data and the published Mg/Ca
258 record from *T. trilobus* at Site 872 (Sosdian et al., 2018). Mg/Ca from a different species, *D. altispira*
259 (Sosdian et al., 2020), is also plotted with an offset, for comparison.

260 Comparison with Site 872 data that is part of the compilation from Sosdian et al. (2018) shows
261 that their $\delta^{11}\text{B}$ data are in line with our dataset (Figure 2B), and all sites examined in the WEP (Sites 806,
262 807, and 872) are above the lysocline (Kroenke et al. 1991). The $\delta^{11}\text{B}$ data for *T. sacculifer* exhibit a
263 significant decrease (4.2‰) from the Miocene to present. Figure 2B also compares the $\delta^{11}\text{B}$ data used in
264 this study with published data from other sites, and shows that raw $\delta^{11}\text{B}$ data for the WEP can be lower
265 than values for other regions.

267 **3.2 Reproducing pCO_2 from ice cores**

268 Validation of air-sea equilibrium in the WEP during the relatively large amplitude late Pleistocene
269 glacial/interglacial cycles was a primary goal for our work. In order to validate our approach, we

270 reconstructed pCO₂ for the last 800 kyr (Fig. 3). The two critical diagnostics we use for method validation
271 are: 1) that the reconstruction of pCO₂ is representative of recent atmospheric CO₂, and 2) that the boron-
272 based reconstruction empirically reproduces the record from ice cores. For the last 800 kyr, reconstructed
273 pCO₂ values for Holes 806A and B and Site 807 are mostly within error of the records from the Vostok
274 and EPICA Dome C ice cores (Fig. 3, Petit et al., 1999, Siegenthaler et al., 2005, Lüthi et al., 2008;
275 compilation from Bereiter et al., 2015), with the exception of two data points at 47 and 79 ka that have
276 lower pCO₂ in comparison to ice core values. Crossplots comparing our data are presented in Figs. 3C,
277 3D, 3E; the slope and intercept are not statistically different from a 1:1 line (p=0.69 and p=0.48). Between
278 MIS 7 and 6, our reconstructions exhibit a decrease in temperature (ΔT) of 1.2°C, an increase in pH (ΔpH)
279 of 0.08 and a decrease in pCO₂ (ΔpCO_2) of 58 ppm. Between stage 3 and 1, we observed an increase of
280 temperature of 2.0°C, a decrease of pH of 0.13 and an increase in pCO₂ of 76 ppm. We also compare
281 results with recent reconstructions in Figs. S1 and S2 (Sosdian et al., 2018; Rae et al., 2021). These results
282 highlight that we are able to reproduce absolute measurements of atmospheric pCO₂ of the ice core record,
283 and reproduce the amplitude of changes between transitions, with uncertainties typical for this type of
284 work (Hönisch et al., 2019). We note that reconstructed pCO₂ uncertainties could potentially be reduced
285 using independent temperature proxies for the WEP such as clumped isotope thermometry (Tripathi et al.,
286 2010; 2014), a technique that is not sensitive to the same sources of error as Mg/Ca thermometry, and
287 therefore is an area planned for future work.

288

289 **3.3 Sea surface temperature in the WEP**

290 Mg/Ca data for the WEP are consistent between studies at Site 806 (Wara et al., 2005; Tripathi et
291 al., 2009, 2011; Nathan and Leckie, 2009) and Site 872 (Sosdian et al., 2018). The Mg/Ca in *T. sacculifer*
292 has to date not shown a pH dependency (Gray and Evans, 2019) but Mg/Ca of *G. ruber* does and was
293 therefore corrected from this effect (see supplemental material). Data for both species were corrected
294 from salinity and seawater Mg/Ca changes. Mg/Ca-temperatures for Site 872 was reconstructed using
295 published data and the same framework we use here, and are presented in Figure 4. Recalculated values
296 for Site 872 are from *D. altispera*, with an offset applied relative to *T. sacculifer*, and show similar
297 variations to our record for the MCO-MMCT periods (Sosdian et al., 2020). Temperatures from Tex₈₆

298 and $U^{K^2}_{37}$ are plotted for comparison but those records are limited to the last 12 and 5 Myrs respectively
299 (Zhang et al., 2014).

300 The Mg/Ca data support high temperatures of 35.2 ± 1.3 °C (2SD, n=11) for the early Miocene
301 until the MMCT, with relatively small (ca. 1°C) change from into the MCO, and larger changes out of the
302 MCO. Similarly warm SST for the MCO were reconstructed in the North Atlantic at Site 608 from Tex_{86}
303 (Super et al., 2018). Despite a gap in our compilation from 11.5 to 9.5 Ma, there is a SST decrease of
304 $\sim 6^\circ\text{C}$ from the MCO to ~ 7 Ma where temperatures similar to present day values are observed. A decline
305 in temperature during the MMCT is coincident with the timing of a constriction of the Indonesian Seaway,
306 the pre-closure of the trans-equatorial circulation and subsequent formation of a proto-warm pool (Nathan
307 and Leckie, 2009; Sosdian et al., 2020). From 12 to 7 Ma, the Mg/Ca-SST record diverges from Tex_{86}
308 and $U^{K^2}_{37}$ -based reconstructions, with higher temperatures. At the same time, a record for the North
309 Atlantic showed a decrease of $\sim 10^\circ\text{C}$ from the MCO to ~ 9 Ma (Super et al., 2018). From 7 Ma to present,
310 the record from multiple proxies – Mg/Ca, Tex_{86} , and $U^{K^2}_{37}$, in the WEP agree.

311

312 **3.4 Scenarios of seawater $\delta^{11}\text{B}$ and alkalinity used for $p\text{CO}_2$ reconstructions**

313 Figures 5 and 6 show the different histories of seawater $\delta^{11}\text{B}$ and alkalinity used for calculations,
314 respectively. Details of calculations are in the Supplemental methods. Following the approach of Tripathi
315 et al. (2009, 2014) and recent literature (Sosdian et al., 2018; Rae et al., 2021), we explored multiple
316 scenarios for the evolution of seawater boron geochemistry (Fig. 5) and alkalinity for calculations of $p\text{CO}_2$
317 (Figs. 6, S1 and S2). During the interval overlapping with the ice core record, we observe that the choice
318 of model used does not make a significant difference in reconstructed values. During earlier time intervals,
319 we see there is a greater divergence, reflecting larger uncertainties in seawater $\delta^{11}\text{B}$ and alkalinity further
320 back in Earth history.

321 Prior to 10 Ma and during the early Pliocene (~ 4.5 to 3.5 Ma), calculations of $p\text{CO}_2$ diverge from
322 published values largely because of the different assumptions each study has used for past seawater $\delta^{11}\text{B}$
323 (Fig. 5). However, we find that when the uncertainty in reconstructed pH is fully propagated, the
324 differences in reconstructed pH values calculated using each of the $\delta^{11}\text{B}_{\text{seawater}}$ histories is not significantly
325 different (Fig. 5 and 6; see also Hönisch et al., 2019). In contrast to the results from Greenop et al. (2017),

326 the record from Raitzsch and Hönisch, (2013) exhibits substantial variations on shorter timescales. Such
327 variability is a challenge to reconcile with the Li isotope record of Misra and Froelich, (2012), given that
328 Li has a shorter residence time than boron while having similar sources and sinks. For the remainder of
329 this study, we use the $\delta^{11}\text{B}_{\text{seawater}}$ history from Greenop et al. (2017) because it is in good agreement with
330 seawater $\delta^7\text{Li}$ (Misra and Froelich, 2012). The recent calculations of seawater pH (Sosdian et al., 2018;
331 Rae et al., 2021) agree with values from our study when uncertainties are taken into account (Fig. 5).

332 The four alkalinity models used in this study diverge prior to 9 Ma, with a maximum difference
333 at ~13 Ma that is also reflected in reconstructed pCO_2 values (Fig. 6). However, all four models yield
334 pCO_2 estimates that are within error of each other when the full uncertainty is considered. Uncertainty in
335 the evolution of seawater alkalinity and seawater $\delta^{11}\text{B}$ leads to differences in the absolute values of pCO_2
336 reconstructed (Fig. S2), and a divergence in pCO_2 values reconstructed that is largest in the Miocene. The
337 two scenarios that produce the highest divergence in values are those calculated using constant alkalinity
338 relative to those calculated using values from McCaves et al. (2016), with a maximum difference at 15.06
339 Ma of up to 250 ppm CO_2 , and with the latter model producing lower values (Fig. 6). Thus, for the MCO,
340 alkalinity is a critical parameter in calculations of absolute pCO_2 values. For the Miocene and earlier
341 intervals, improved constraints on past secular variations of seawater $\delta^{11}\text{B}$ and alkalinity will yield more
342 accurate reconstructions of pCO_2 .

343 For the remainder of this paper, we use the model of Caves et al. (2016) to estimate alkalinity and
344 $\delta^{11}\text{B}_{\text{seawater}}$ determined by Greenop et al. (2017). We note that two recent syntheses of boron isotope data
345 have been published and compare our results to these findings (Figs. 8 and S2). Sosdian et al. (2018)
346 reports values that are in line with our results in the Miocene but this study does not replicate results from
347 ice cores. Rae et al. (2021) presents reconstructed values that are higher in the Miocene, due to the
348 utilization of different scenarios of seawater $\delta^{11}\text{B}$ and alkalinity compared to this work.

349

350 **3.5 Time intervals**

351 **3.5.1 Miocene**

352 The study of Miocene climate is thought to provide a useful analog for changes associated with
353 global warming and melting of polar ice, in concert with ocean circulation (Holbourn et al., 2013). The

354 Miocene epoch (23-5.3 Ma) is characterized by a warm interval, the Miocene Climate Optimum (~17-
355 14.7 Ma - MCO), and an abrupt cooling during the Middle Miocene Climate Transition (~14-13 Ma –
356 MMCT) that led to the expansion of ice on Antarctica and Greenland. Climate modeling supports a role
357 for decreasing CO₂ in this transition (DeConto and Pollard, 2003). However, reconstructions for the
358 Miocene are still relatively limited (Sosdian et al., 2018; Rae et al., 2021). Current boron isotope and
359 alkenone-based pCO₂ reconstructions support higher pCO₂ during the MCO and a decrease over the
360 MMCT (Sosdian et al. 2018; Stoll et al., 2019; Tanner et al., 2020), consistent with what was previously
361 inferred from B/Ca (Tripathi et al., 2009, 2011).

362 We applied the same framework we used for calculations at Sites 806 and 807 to published boron
363 isotope data from Site 872 (Sosdian et al., 2018) in order to extend the WEP record to the early Miocene
364 (Figs. 7, 8). The Miocene data between Sites 806 and 872 do not overlap as both are low in resolution,
365 but do show excellent correspondence in their trends in δ¹¹B and reconstructed pH. For example, the
366 closest datapoints in time at the two sites are at 15.6 Ma at Site 806 with a δ¹¹B=14.47± 0.21 ‰, and at
367 16.7 Ma at Site 872, with a δ¹¹B=15.12± 0.25 ‰. The pH values we reconstruct are within error of
368 published estimates from Site 872 (Sosdian et al. 2018, Figs. 7D and 8D). Collectively, these data suggest
369 the early Miocene WEP was characterized by a mixed-layer pH of 8.1 ± 0.1 (2 SD, n=4) between 19.4
370 and 21.8 Ma, which decreased to reach a minimum during the MCO of 7.7 (±_{0.14}^{0.11}) ‰.

371 Given the sensitivity in absolute pCO₂ to assumptions about the second carbonate system
372 parameter, a few scenarios were explored for the combined 806/807/872 reconstructed pH values. For all
373 alkalinity scenarios we used, reconstructed pCO₂ shows an increase from the Early Miocene to the MCO,
374 with the highest values in the MCO. Recalculated pCO₂ for Site 872 between 19.4 and 21.8 Ma is 232 ±
375 92 ppm (2 SD, n=4), lower but within error of the ones presented in Sosdian et al. (2018) and also within
376 error of a constant alkalinity scenario (Fig 8D). The main difference between reconstructions is when
377 comparing the same data recalculated in Rae et al. (2021) that show higher pCO₂ between 19.4 and 21.8
378 Ma, with an average value of 591 ± 238 ppm (2 SD, n=4) for Site 872, because of the different
379 assumptions used in their study and ours. This difference is important because that would imply a
380 relatively high and stable pCO₂ from the early Miocene to MCO, which would imply a decoupling
381 between pCO₂ and temperature with no pCO₂ change during an interval of decreasing benthic δ¹⁸O.

382 However, our reconstructed pCO₂ increase towards the MCO is in line with the observed benthic δ¹⁸O
383 decrease and δ¹³C increase and suggest a coupling between temperature and pCO₂ over this period. We
384 note that overall, Mg/Ca-SSTs are warm (>32 °C), and there are relatively small changes in Mg/Ca-SST
385 from the early Miocene into the MCO in the WEP.

386 The highest pCO₂ values we reconstruct are during the MCO (Fig. 6E). For the MCO, our
387 estimates are 511 ± 201 ppm (2 SD, n=3, Table 2). The middle Miocene values we reconstruct are in line
388 with previous studies (Greenop et al., 2014; Sosdian et al., 2018). Published δ¹¹B-based reconstructions
389 also support higher pCO₂ for the MCO of ~350-400 ppm (Foster et al., 2012) or 300-500 ppm (Greenop
390 et al., 2014) that was recalculated by Sosdian et al. (2018) to be ~470-630 ppm depending on the model
391 of δ¹¹B_{seawater} chosen. During the MCO relative maxima in pCO₂, our data support very warm sea surface
392 temperatures in the WEP (35.6°C ± 0.6°C 2SD, n=3; Fig. 8C), that merits further examination in future
393 studies. In fact, the highest temperatures recorded in our samples occur when there is a minimum in the
394 global composite record of δ¹⁸O of benthic foraminifera (Zachos et al., 2001, 2008; Tripati and Darby,
395 2018).

396 During the MMCT, we find evidence for changes in pCO₂ and temperature in the WEP (Fig. 8).
397 From 13.5 to 12.7 Ma, we reconstruct an increase of pH ~0.21 and a major decrease of pCO₂ of ~215
398 ppm during an interval highlighted by Flower and Kennett, (1996), who observed changes in δ¹⁸O
399 indicative of rapid East Antarctic Ice Sheet growth, and enhanced organic carbon burial with a maximum
400 δ¹³C reached at ~13.6 Ma (Shevenell et al., 2004; Holbourn et al., 2007). As discussed in section 3.4 the
401 alkalinity model used for the calculations have an important impact during the Miocene which is likely
402 responsible for the different absolute pCO₂ values over the MCO. In comparison, a scenario of constant
403 alkalinity would lead to a pCO₂ during the MCO of 714 ± 313 ppm (2 SD, n=3) and a decrease of ~540
404 ppm during the MMCT. Both those reconstructions could simulate the large-scale advance and retreat of
405 Antarctic ice with such low pCO₂ values (Gasson et al., 2016). At the same time, we find evidence for a
406 decline in SST of 3.4°C to a minimum of 33.3°C. The synchronous shifts in the δ¹³C and δ¹⁸O of benthic
407 foraminifera are consistent with increased carbon burial during colder periods, thus feeding back into
408 decreasing atmospheric CO₂, and supporting the hypothesis that the drawdown of atmospheric CO₂ can
409 in part, be explained by enhanced export of organic carbon.

410 The resolution of our data during the late Miocene is low, with a data gap from 12.5 to 9.2 Ma,
411 and another gap between 6.5 and 5 Ma. We note the pCO₂ peak at ~9 Ma observed by Sosdian et al.
412 (2018) is not seen in our record although this is likely due to the low resolution of our dataset. Between
413 9.5 and 7.1 Ma we find evidence for a decrease in atmospheric CO₂ of 100 ppm associated with a decrease
414 in temperature of 1.3 °C. pCO₂ estimates derived from alkenones for Site 1088 (Tanner et al., 2020) do
415 not show the same trend as boron-based reconstructions from the WEP or other regions (Figure 6), but
416 this perhaps is unsurprising given the oceanographic setting of Site 1088.

417

418 **3.5.2 Pliocene**

419 Oxygen isotope data from a global benthic foraminiferal stack show that the Pliocene epoch (5.3-
420 2.6 Ma) was initially characterized by warm conditions followed by the intensification of glaciation that
421 occurred in several steps, including during MIS M2 (3.312-3.264 Ma), followed by the Middle Pliocene
422 Warm Period (Lisiecki and Raymo, 2005). The Middle Pliocene Warm Period (mPWP – 3.29-2.97 Ma)
423 is considered a relevant geological analogue for future climate change given ~3°C warmer global
424 temperatures and sea levels that were ~20 m higher than today (Dutton et al., 2015; Haywood et al., 2016),
425 and is a target for model intercomparison projects, for which accurate paleo-atmospheric pCO₂ estimates
426 are critical (Haywood et al., 2016).

427 Figure 9 shows that during the Early Pliocene warm interval, from 4.7 to 4.5 Ma, we calculate
428 high pCO₂ values of 419 ± 119 ppm (2 SD, n=3, Table 2). The pCO₂ data we report provide a higher data
429 density for the Early Pliocene, with a trend that is in line with the reconstruction from Rae et al. (2021).
430 Our data support values of 530 ± 110 ppm over the mPWP (2 SD, n = 4), higher than previously published
431 data (Figs. 9, S2 and Table 2), although we acknowledge our low data density may not fully sample
432 variability over this period. The similarity between our reconstructed values and those published for Site
433 871 in the Indian Ocean (Sosdian et al., 2018) suggests that changes in Indonesian through-flow do not
434 induce substantial changes in air-sea exchange in the WEP.

435 The warmth and local pCO₂ maxima of the mPWP (mid-Pliocene Warm Period) was followed by
436 a strong decrease of temperature in upwelling and high latitude regions during from 3.3-2.7 Ma,
437 coincident with glacial intensification in the Northern Hemisphere. This climate transition was

438 hypothesized to be driven by the closure of the Panama seaway the opening of the high latitudes and
439 subsequent modifications of oceanic circulation (Haug and Tiedemann, 1998). However, modeling from
440 Lunt et al. (2008) supports an additional major role for CO₂ in the glaciation. pCO₂ thresholds have been
441 proposed to explain the intensification of Northern Hemisphere Glaciation, with values proposed ranging
442 from 280 ppm (DeConto et al., 2008) to 200 to 400 ppm (Koenig et al., 2011).

443 The pCO₂ concentrations that we calculate indicates a reduction to 350 ppm by 2.7 Ma, ~280 ppm
444 by 2.6 Ma, and ~210 ppm by 2.4 Ma, in several steps. These results support roughly a halving of CO₂
445 values when compared to values of ~530 ppm at 3.3 Ma. These values are consistent with the pCO₂
446 thresholds proposed by both DeConto et al. (2008) and Koenig et al. (2011) for the intensification of
447 Northern Hemisphere glaciation and the low atmospheric CO₂ (280 ppmv) scenario from Lunt et al.
448 (2008). Mg/Ca SST decline from 30°C to 26°C, supporting an Earth System sensitivity of ~4°C/doubling
449 of CO₂ over this range, although given uncertainties, higher values of ~6°C/doubling of CO₂ that have
450 recently been proposed (Tierney et al., 2020) can not be excluded.

451 We speculate that associated with Pliocene glacial intensification, at 4.42, 3.45 and 2.67 Ma, it is
452 possible that the declines in CO₂ and ice growth in turn drove substantial changes in pole-to-equator
453 temperature gradients and winds, that in turn may have impacted iron cycling (Watson et al., 2000;
454 Robinson et al., 2005; Martinez-Garcia et al., 2011), stratification (Toggweiler, 1999; Sigman et al.,
455 2010), and other feedbacks that impact the amplitude of glacial/interglacial cycles and have been
456 implicated as factors that could have contributed to Pliocene glacial intensification. Specifically, as the
457 mean climate state of the planet became cooler, and glacial-interglacial cycles became larger in amplitude,
458 enhanced windiness and dust transport and upwelling during glacials (Martinez-Boti et al., 2015b) may
459 have enhanced iron fertilization and subsequent carbon export (Martinez-Garcia et al., 2011). While data
460 resolution are limited, we speculate this could explain why glacial/interglacial amplitudes in WEP pCO₂
461 values decrease from the MPWP towards the Pleistocene, whereas variations in δ¹⁸O are increasing – a
462 speculation that could be tested with increased data resolution.

463

464 3.5.3 Pleistocene

465 During the Pleistocene (2.58-0.01 Ma), the climate system experienced a transition in
466 glacial/interglacial (G/I) variability from low amplitude, higher frequency and obliquity-dominated
467 oscillations (i.e., ~ 41 kyr) of the late Pliocene to the high amplitude, lower frequency and eccentricity-
468 dominated cycles (i.e., ~100 kyr) of the last 800 kyr. This transition is termed the Middle Pleistocene
469 Transition (1.2-0.8 Ma – MPT). Questions have been raised about the role of atmospheric CO₂ during this
470 transition, including using boron-based proxies (Hönisch et al., 2009; Tripathi et al., 2011; Chalk et al.,
471 2017). Previous boron isotope studies for ODP Sites 668 and 999 in the tropical Atlantic Ocean have
472 suggested that a decline in atmospheric CO₂ did occur during glacial periods in the MPT, but not during
473 interglacials (Hönisch et al., 2009; Chalk et al., 2017; Dyez et al., 2018).

474 Our pCO₂ concentrations for Sites 806/807 reported here are in good agreement with those
475 determined from ice cores from the early Pleistocene (Yan et al., 2019, Figs. 9 and 10), and with the
476 boron-derived pCO₂ from a recent compilation (Rae et al., 2021). Results for the MPT are broadly in the
477 range of values reported by Hönisch et al. (2009) and Chalk et al. (2017). Although our data are relatively
478 limited, we note they have greater resolution for the middle and later part of the transition than prior
479 publications that have drawn conclusions about the MPT (Hönisch et al., 2009; Chalk et al., 2017; Dyez
480 et al., 2018) (Fig. 10D) and therefore we explore their implications.

481 Taken alone, or when combined with the published data from Chalk et al. (2017) (that is also based
482 on MC-ICPMS), our results support a possible reduction of both glacial and interglacial pCO₂ values. We
483 also find evidence that during the MPT, glacial pCO₂ declined rapidly from 189 (±30) ppm at MIS 36
484 (Chalk et al., 2017) to reach a minimum of 170 (\pm_{24}^{52}) ppm during MIS 30. We note that pCO₂
485 concentrations are within error when uncertainty is fully propagated, and then remained relatively stable
486 until the end of the MPT whereas interglacial pCO₂ values decrease gradually to reach post-MPT values.

487 In our record for the last 16 Myr, the lowest pCO₂ is recorded at MIS 30 during the MPT, with
488 values of 164 (\pm_{35}^{44}) ppm, which supports an atmospheric CO₂ threshold that leads to ice sheet stability.
489 During this transition, the pCO₂ threshold needed to build sufficiently large ice sheets that were able to
490 survive the critical orbital phase of rising obliquity to ultimately switch to a 100 kyr world, was likely
491 reached at MIS 30. The multiple feedbacks resulting from stable ice sheets (iron

492 fertilization/productivity/changes in albedo/ changes in deep water formation) might have sustained larger
493 mean global ice volumes over the subsequent 800 kyr. An asymmetrical decrease between pCO₂ values
494 during interglacials relative to glacials, with glacials exhibiting the largest change across the MPT, would
495 have led to increased sequestration of carbon during glacials in the 100 kyr world, as discussed by Chalk
496 et al. (2017), with increased glacial dust input and iron fertilization.

497

498 **3.6 Changes in volcanic activity and silicate weathering, and long-term pCO₂**

499 On million-year timescales, atmospheric CO₂ is mainly controlled by volcanic activity and silicate
500 weathering. Over the last 16 Myr, two relative maxima in atmospheric pCO₂ are observed in our record,
501 one during the MCO (at 15.67 Ma) and a second around the late Miocene/early Pliocene (beginning at
502 4.7 and 4.5 Ma) (Fig. 11), though the timing for the latter is not precise. The strong pCO₂ increase from
503 the early Miocene to MCO is timely with increasing volcanic activity (Foster al. 2012), associated with
504 the eruption of the Columbia River Flood Basalts (Hooper et al., 2002; Kasbohm and Schoene, 2018),
505 with recent geochronologic evidence published supporting higher eruption activity between 16.7 and 15.9
506 Ma (Kasbohm and Schoene, 2018) reinforcing the idea of an episodic pCO₂ increase during the MCO due
507 to volcanic activity.

508 The second CO₂ peak could correspond to observed global increased volcanism in the early/middle
509 Pliocene (Kennett and Thunell, 1977; Kroenke et al., 1993), and/or a change of silicate weathering regime.
510 Strontium and lithium isotopes (^{87/86}Sr and δ⁷Li) have been used as proxy for silicate weathering activity.
511 Although the strontium isotope record exhibits a monotonous increase, lithium isotope data (Misra and
512 Froelich, 2012) are more variable with a transition from a period of increase seawater δ⁷Li (e.g. non-
513 steady state weathering) to stable seawater δ⁷Li (e.g., steady state weathering) beginning at roughly 6.8
514 Ma (Fig. 11).

515 It is also interesting to note that the changes in δ⁷Li (Fig. 11B) in the early Miocene to the MCO
516 are in line with changes in pCO₂. Before 18.5 Ma, the pCO₂ is relatively stable, δ⁷Li is increasing
517 representative of a non-steady state weathering. From 18.6 to 16.7 the δ⁷Li decrease of about 2‰, this
518 decrease can inform on decreasing weathering rate and this decrease is associated with an increase in
519 pCO₂. Between 16.7 and 15.9 Ma, when the eruption of the Columbia River Flood Basalts is maximum

520 the $\delta^7\text{Li}$ increases, in line with higher weathering due to higher atmospheric CO_2 and the presence of fresh
521 silicate rocks. The $\delta^7\text{Li}$ decreases again until the end of the MCO ~ 14.7 Ma, in line with a decrease in the
522 eruption rate and sustaining high atmospheric CO_2 , then, a constant increase is observed until the early
523 Pliocene where the change toward a steady in weathering regime occurs, this increase in $\delta^7\text{Li}$ is also
524 consistent with the decrease in pCO_2 observed until the early Pliocene.

525

526 **3.9 Outlook and Conclusions**

527 We developed a reconstruction of atmospheric pCO_2 based on $\delta^{11}\text{B}$ of planktic foraminifera from
528 ODP Sites 806 and 807 located in the Western Equatorial Pacific for the past 16 million years and
529 extended the record to 22 Ma by processing data from Site 872. Our study represents the first long-term
530 reconstruction for the Neogene derived from boron isotopes from the Pacific Ocean. We build on past
531 efforts to reconstruct atmospheric pCO_2 using different proxies from this region, including from carbon
532 isotopes in marine organic matter (Rayno et al., 1996) and alkenones (Pagani et al., 2010), as well as
533 foraminiferal B/Ca ratios (Tripathi et al., 2009, 2011), all of which have been shown to have a number of
534 complexities and potential sources of systematic error (e.g., Tripathi et al., 2011). It also builds on efforts
535 using boron isotopes in other regions using MC-ICP-MS (Seki et al., 2010; Foster et al., 2012, 2014;
536 Greenop et al., 2014; Martinez-Boti et al., 2015b; Stap et al., 2016; Chalk et al., 2017; Dyez et al., 2018;
537 de la Vega et al., 2020), and our recent work constraining fractionation factors and measuring small
538 samples of foraminifera. Although the record is not continuous, with variable resolution, it captures both
539 long-term and short-term variability associated with several key transitions and demonstrates the utility
540 of these sites for future higher resolution study.

541 As expected, these data generally reproduce the pCO_2 record from ice cores, consistent with the
542 sites being in equilibrium with the atmosphere. The MCO has higher pCO_2 than reconstructions from
543 other sites, with values estimated as 511 ± 201 ppm (2 SD, $n=3$), likely linked to the eruption of the
544 Columbia River Flood Basalts, with values declining into the early Pliocene, including during Pliocene
545 glacial intensification. The changes in pCO_2 we observed are in line with changes in $\delta^7\text{Li}$, proxy of silicate
546 weathering, future modelling on those records will provide helpful insights.

547 We find support for a larger reduction in glacial $p\text{CO}_2$ during the MPT compared to interglacial
548 $p\text{CO}_2$, and a minimum in $p\text{CO}_2$ during glacial MIS 30. These findings confirm a role for CO_2 in the
549 transition from a 41 kyr to a 100 kyr world.

550 Higher-resolution boron isotope records from the WEP would allow for further resolution of these
551 changes. Additional constraints on temperature, such as from clumped isotopes (Tripathi et al., 2010) in
552 the WEP (Tripathi et al., 2014), could allow for uncertainties in $p\text{CO}_2$ estimates from boron isotopes to be
553 reduced and for new constraints on Earth system climate sensitivity. Future constraints on the vertical
554 structure of the tropical Pacific during these transitions may also potentially be illuminating.

555 **Code/ data availability**

557 All data are available in the supplemental materials.

559 **Author Contribution**

560 AT wrote the proposals that funded the work and provided the samples. All authors contributed to the
561 experimental design. MG performed the measurements with assistance from SM. MG conducted the data
562 analysis. MG drafted the paper, which was edited by all authors. Interpretation was led by MG, AT, and
563 SM with input from RE.

565 **Competing interests**

566 The authors declare that they have no conflict of interest.

568 **Acknowledgments**

569 The authors wish to thank the Tripathi Lab, including Lea Bonnin and Alexandra Villa, for assistance with
570 picking samples; the IODP core repository for provision of samples; Mervyn Greaves for technical
571 support and use of laboratory space at the University of Cambridge; Yoan Germain, Emmanuel
572 Ponzevera, Céline Liorzou and Oanez Lebeau for technical support and use of laboratory space at IUEM
573 and Ifremer (Plouzané, France). We thank Thomas Chalk, another anonymous reviewer, and Hubertus
574 Fischer for their helpful comments on the manuscript, and Mathis Hain for discussion of this work.

575

576 **Financial support**

577 This research is supported by DOE BES grant no. DE-FG02-13ER16402 to AKT, by the International
578 Research Chair Program that is funded by the French government (LabexMer ANR-10-LABX-19-01) to
579 AKT and RAE, and IAGC student research grant 2017.

1005 **Figure captions**

1006 **Figure 1:** Modern hydrography of sites. **A.** Map of air-sea pCO₂ ($\Delta p\text{CO}_2$, ppm, data from Takahashi et
1007 al. (2014) and plotted using Ocean Data View from Schlitzer, (2016) showing the location of ODP
1008 Sites 806 and 807 (black circles) and Site 872 (black square, Premoli et al., 1993). Depth profiles are
1009 for preindustrial parameters, **B.** pH calculated from GLODAP database and corrected from
1010 anthropogenic inputs, **C.** Boron isotopic composition of borate ion ($\delta^{11}\text{B}_{\text{borate}}$) with associated
1011 propagated uncertainties.

1012 **Figure 2:** Foraminiferal data for the Miocene to Recent. **A.** Benthic foraminiferal $\delta^{18}\text{O}$ data (blue line
1013 – stack from Lisiecki and Raymo, 2005; black line – compilation from Zachos et al., 2008). **B.** $\delta^{11}\text{B}$ of
1014 *T. sacculifer* (blue circles) and *G. ruber* (blue triangles) at Sites 806 (light blue), 807 (dark blue), Grey
1015 filled square are data from Site 872 located in the WEP (Sosdian et al., 2018). Open symbols are $\delta^{11}\text{B}$
1016 data from published studies (Hönisch and Hemming, 2009; Seki et al., 2010; Foster et al., 2012;
1017 Greenop et al., 2014; Martinez-Boti et al., 2015a; Chalk et al., 2017; Dyez et al., 2018; Sosdian et al.,
1018 2018; de la Vega et al., 2020), grey open symbols are *T. sacculifer*, brown open symbols are for *G.*
1019 *ruber*. **C.** Mg/Ca ratios of *T. sacculifer* and *G. ruber* at Sites 806, 807 and fourth-order polynomial
1020 regression from Sosdian et al. (2020) representing secular variations of Mg/Ca_{sw} (blue dotted line). **E.**
1021 Calculated weight per shell for *T. sacculifer* and *G. ruber*. For Panels B-D: Circles = *T. sacculifer*,
1022 Triangles = *G. ruber*.

1023 **Figure 3:** **A.** Reconstruction of surface pCO₂ for the past 0.8 Myr from *T. sacculifer* at ODP Sites 806
1024 and 807. Planktonic foraminiferal $\delta^{18}\text{O}$ at site 806 with isotope stages labeled (black line – Medina-
1025 Elizalde and Lea, 2005) and benthic foraminiferal $\delta^{18}\text{O}$ stack (grey line - Lisiecki and Raymo, 2005).
1026 **B.** pCO₂ values calculated from boron isotopes (colored symbols - this study) with data from the
1027 literature (open gray triangles – data recalculated in Rae et al., 2021) and ice core pCO₂ (black line –
1028 Bereiter et al., 2015). Data from the two sites we examined reproduces the absolute values and
1029 amplitude of atmospheric pCO₂ as determined from ice cores, thereby validating our methodology. **C.**
1030 Cross plot for the last 0.8 Myr of $\delta^{11}\text{B}_{T. sacculifer}$ from this study and $\delta^{18}\text{O}_{G. ruber}$ from site 806 (Medina-
1031 Elizalde and Lea, 2005) (Linear regression: p=0.7). **D.** Cross plot for the last 0.8 Myr of pCO₂*T. sacculifer*
1032 from this study and $\delta^{18}\text{O}_{G. ruber}$ from site 806 (Medina-Elizalde and Lea, 2005) (Linear regression: p=0.9)
1033 and **E.** Cross plot for the last 0.8 Myr of pCO₂*T. sacculifer* from this study and pCO₂_Vostok (from ice core,
1034 Bereiter et al., 2015) (Linear regression: p=0.3, R²=0.09).

1035 **Figure 4:** Compilation of temperature from site 806 in the WEP. Mg/Ca based temperature were
1036 derived using the same framework (see supplemental information). Blue filled symbols are from Sites
1037 806 and 807, filled gray squares are data from Site 872 (Sosdian et al., 2018). Open symbols are SST
1038 derived from Mg/Ca at Site 806 (Wara et al., 2005; Tripathi et al., 2009; Nathan and Leckie, 2009).
1039 Tex₈₆ and U^K₃₇ are also plotted for comparison (Zhang et al., 2014). Blue line is a smooth line
1040 (Lowess) going through the data.
1041

1042 **Figure 5:** Different models for the evolution of the boron geochemistry explored as part of this work.
1043 Due to the 1‰ uncertainty propagated for $\delta^{11}\text{B}_{\text{seawater}}$, all scenarios yield reconstructed seawater pH
1044 values that are within error of each other. Propagated uncertainties were calculated using eq. S14 (see
1045 Supplement). **A.** Different models for $\delta^{11}\text{B}_{\text{seawater}}$ used for the reconstruction of pCO₂ in this study (blue
1046 – Lemarchand et al., 2000; green – Greenop et al., 2017; red – Raitzsch and Hönisch, 2013). **B.**
1047 Reconstructed pH based on our measured $\delta^{11}\text{B}_{\text{carbonate}}$ values using different models for $\delta^{11}\text{B}_{\text{seawater}}$ (blue
1048 – Lemarchand et al., 2000; green – Greenop et al., 2017; red – Raitzsch and Hönisch, 2013), compilation
1049 pH from Sosdian et al. (2018) (open squares) and Rae et al. (2021) (open triangles) are also shown for
1050 comparison.
1051

1052 **Figure 6:** Different models for the evolution of a second carbonate (e.g. alkalinity) system parameter
1053 explored as part of this work. The propagated uncertainties were calculated using eq. S16 (see
1054 Supplement). **A.** Different models for alkalinity used for the reconstruction of pCO₂ in this study

1055 (brown – constant alkalinity of 2330 $\mu\text{mol/kg}$, blue - Ridgwell and Zeebe, 2005; green - Tyrell and
 1056 Zeebe, 2004; violet - Caves et al., 2016. Colored symbols are reconstructed pCO_2 based on our
 1057 measured $\delta^{11}\text{B}_{\text{carbonate}}$ values, alkalinity scenario and $\delta^{11}\text{B}_{\text{seawater}}$ from Greenop et al., 2017; open
 1058 squares are pCO_2 compilation from Sossdian et al. (2018), open triangles are from compilation from
 1059 Rae et al. (2021), black symbols are from site 872. **B.** Reconstructed pCO_2 using constant alkalinity of
 1060 2330 $\mu\text{mol/kg}$ and $\delta^{11}\text{B}_{\text{seawater}}$ from Greenop et al. (2017). **C.** Reconstructed pCO_2 using constant
 1061 alkalinity scenario from Ridgwell and Zeebe, (2005) and $\delta^{11}\text{B}_{\text{seawater}}$ from Greenop et al. (2017). **D.**
 1062 Reconstructed pCO_2 using constant alkalinity scenario from Tyrell and Zeebe, (2004) and $\delta^{11}\text{B}_{\text{seawater}}$
 1063 from Greenop et al. (2017). **E.** Reconstructed pCO_2 using constant alkalinity scenario from Caves et
 1064 al., (2016) and $\delta^{11}\text{B}_{\text{seawater}}$ from Greenop et al. (2017). Stars indicate pCO_2 values reconstructed from
 1065 alkenones by Tanner et al. (2020) (simulation 6) at Site 1088 in the Southern Ocean.

1066
 1067 **Figure 7:** Proxy data for the past 22 million years in the Western Equatorial Pacific compared to benthic
 1068 oxygen isotope data. **A.** Benthic $\delta^{18}\text{O}$ (blue line – stack from Lisiecki and Raymo, 2005; black line –
 1069 compilation from Zachos et al., 2008). **B.** Benthic $\delta^{13}\text{C}$ (black line – compilation from Zachos et al.,
 1070 2008). **C to E,** colored is indicating the site (filled light blue=806, filled dark blue=807), symbols
 1071 represent the species (circle=*T. sacculifer* and triangle=*G. ruber*), filled grey squares are recalculated
 1072 data based on Sossdian et al. (2018) at site 872. **C.** SST reconstructed at ODP Sites 806 and 807 using
 1073 Mg/Ca ratios (see supplemental informations for reconstruction details), open symbols are
 1074 reconstructed temperature based on literature Mg/Ca at site 806 (see text or Fig. 4). **D.** Seawater pH
 1075 reconstructed from $\delta^{11}\text{B}$ of *T. sacculifer* and *G. ruber* using $\delta^{11}\text{B}_{\text{seawater}}$ from Greenop et al. (2017) (refer
 1076 to text and supplement for calculations, this study), open squares are compilation data from Sossdian et
 1077 al. (2018) and open triangles are compilation from Rae et al. (2021). **E.** Reconstructed pCO_2 (ppm)
 1078 using boron-based pH and alkalinity from Caves et al. (2016), data presented are from this study.
 1079 Propagated uncertainties are given by eq. S17 for the dark blue envelope, while the light blue envelope
 1080 are the uncertainties calculated based on eq. S16 (taking into account uncertainty on $\delta^{11}\text{B}_{\text{seawater}}$). Cross
 1081 symbols are original pCO_2 calculated in Sossdian et al. (2018) at site 872; asterix symbols are calculated
 1082 pCO_2 at site 872 from Rae et al. (2021).

1083 **Figure 8:** Proxy data from 22 to 6 million years, including the Middle Miocene Climate Transition
 1084 (MMCT) and Miocene Climate Optimum (MCO), in the Western Equatorial Pacific compared to
 1085 benthic oxygen isotope data. **A.** Benthic $\delta^{18}\text{O}$ (black line – compilation from Zachos et al., 2008). **B.**
 1086 Benthic $\delta^{13}\text{C}$ (black line – compilation from Zachos et al., 2008). **C and D,** colored is indicating the
 1087 site (filled light blue=806, filled dark blue=807), symbols represent the species (circle=*T. sacculifer*
 1088 and triangle=*G. ruber*), filled grey squares are recalculated data based on Sossdian et al. (2018) at site
 1089 872. **C.** SST reconstructed at ODP Sites 806 and 807 using Mg/Ca ratios (see supplemental informations
 1090 for reconstruction details), open symbols are reconstructed temperature based on literature Mg/Ca at
 1091 site 806 (see text or Fig. 4). **D.** Reconstructed pCO_2 (ppm) from this study (blue symbols) using boron-
 1092 based pH and alkalinity from Caves et al. (2016). Propagated uncertainties are given by eq. S17 for the
 1093 dark blue envelope, while the light blue envelope reflects the uncertainties calculated based on eq. S16
 1094 (taking into account uncertainty on $\delta^{11}\text{B}_{\text{seawater}}$). Orange datapoints and envelope are calculated pCO_2
 1095 and associated uncertainty from our study using our framework and a constant alkalinity scenario. Open
 1096 squares are compilation data from Sossdian et al. (2018). Cross symbols are original pCO_2 calculated in
 1097 Sossdian et al. (2018) at site 872; asterix symbols are calculated pCO_2 at site 872 from Rae et al. (2021).

1098 **Figure 9:** Proxy data from 7 to 1 million years, including the Warm Pliocene Transition (WPT), in the
 1099 Western Equatorial Pacific compared to benthic oxygen isotope data. **A.** Benthic $\delta^{18}\text{O}$ (black line –
 1100 compilation from Zachos et al., 2008). **B.** Benthic $\delta^{13}\text{C}$ (black line – compilation from Zachos et al.,
 1101 2008). **C and D,** colored is indicating the site (filled light blue=806, filled dark blue=807), symbols
 1102 represent the species (circle=*T. sacculifer* and triangle=*G. ruber*), filled grey squares are recalculated
 1103 data based on Sossdian et al. (2018) at site 872. **C.** SST reconstructed at ODP Sites 806 and 807 using
 1104 Mg/Ca ratios (see supplemental informations for reconstruction details), open symbols are
 1105 reconstructed temperature based on literature Mg/Ca at site 806 (see text or Fig. 4). **D.** Reconstructed
 1106 pCO_2 (ppm) from this study (blue symbols) using boron-based pH and alkalinity from Caves et al.

1107 (2016). Propagated uncertainties are given by eq. S17 for the dark blue envelope, while the light blue
1108 envelope reflects the uncertainties calculated based on eq. S16 (taking into account uncertainty on
1109 $\delta^{11}\text{B}_{\text{seawater}}$). Open squares are pCO₂ compilation from Sosdian et al. (2018), open triangles are from
1110 compilation from Rae et al. (2021). In black are published estimates from ice core data (circles - Yan
1111 et al., 2019).

1112 **Figure 10:** Proxy data from 1.5 to 0.5 million years, including the Middle Pleistocene Transition
1113 (MPT), in the Western Equatorial Pacific compared to benthic oxygen isotope data. **A.** Benthic $\delta^{18}\text{O}$
1114 (blue line – stack from Lisiecki and Raymo, 2005). **B.** Benthic $\delta^{13}\text{C}$ (black line – compilation from
1115 Zachos et al., 2008). **C and D** colored is indicating the site (filled light blue=806, filled dark blue=807),
1116 symbols represent the species (circle=*T. sacculifer* and triangle=*G. ruber*), filled grey squares are
1117 recalculated data based on Sosdian et al. (2018) at site 872. **C.** SST reconstructed at ODP Sites 806 and
1118 807 using Mg/Ca ratios (see supplemental informations for reconstruction details), open symbols are
1119 reconstructed temperature based on literature Mg/Ca at site 806 (see text or Fig. 4). **D.** Reconstructed
1120 pCO₂ (ppm) from this study (blue symbols) using boron-based pH and alkalinity from Caves et al.
1121 (2016). Propagated uncertainties are given by eq. S17. In black are published estimates from ice core
1122 data (line – Bereiter et al., 2015; black circles - Yan et al., 2019). Open triangles are from compilation
1123 from Rae et al. (2021).

1124 **Figure 11:** Proxy data from 1.5 to 0.5 million years, including the Middle Pleistocene Transition
1125 (MPT), in the Western Equatorial Pacific compared to benthic oxygen isotope composites. **A.** Benthic
1126 $\delta^{18}\text{O}$ (blue line – compilation from Lisiecki and Raymo, 2005, black line – compilation from Zachos et
1127 al. 2008). **B.** Records from Lithium isotopes ($\delta^7\text{Li}$, orange, Misra and Froelich, 2012) and Strontium
1128 isotopes ($^{87/86}\text{Sr}$, grey, Hodell et al., 1991, Farrel et al., 1995, Martin et al., 1999, Martin et al., 2004),
1129 both proxies for silicate weathering. Orange arrows represent the different weathering regimes as
1130 indicated by the $\delta^7\text{Li}$, black crosses are indication when changes in weathering regime occurs. **C.**
1131 Reconstructed pCO₂ (ppm) using boron-based pH and alkalinity from Caves et al. (2016), colored is
1132 indicating the site (filled light blue=806, filled dark blue=807), symbols represent the species (circle=*T.*
1133 *sacculifer* and triangle=*G. ruber*), filled grey squares are recalculated data based on Sosdian et al. (2018)
1134 at site 872. Propagated uncertainties are given by eq. S17 for the dark blue envelope, while the light
1135 blue envelope are the uncertainties calculated based on eq. S16 (taking into account uncertainty on
1136 $\delta^{11}\text{B}_{\text{seawater}}$). Also shown are timing of major events. The rose band and dark rose band indicate eruption
1137 of the Columbia River flood basalts (Hooper et al., 2002) and time of maximum eruption (Kasbohm
1138 and Schoene, 2018), respectively.
