

Overview

This study by Higgins et al. investigates the Southern Hemisphere (New Zealand, to be specific) tree growth response to volcanic events. In contrast to previous studies that barely found any response, this study presents evidence of clearly identified responses. The authors conducted superposed epoch analysis (SEA) on tree-ring chronologies by species and by sites, and by groups of cedar chronologies as a further analysis. With these analyses, they found that the volcanic response of the New Zealand trees could be positive, negative, and neutral, and site-related factors appear to be more important than species. Then they built temperature reconstructions based on these tree-ring chronologies, on which they conducted SEA, comparing to that of the climate model simulations. The comparison shows agreement between simulations and reconstructions, indicating that the New Zealand trees are reliable volcanism recorders.

In my opinion, these exciting results are of importance and interest to the community, and can stimulate further studies on Southern Hemisphere trees. The manuscript is overall in good quality, with a clear structure, and analyses being thorough and to the point. I have only a few minor suggestions that I list below. Once those have been addressed, I recommend the work be accepted for publication.

Thank you for your review. Please find the responses to your specific comments in blue below.

Specific comments

L28: "the" is a typo.

Yes, thank you.

Figs. 3, S1: We still need the y-axis label for chronologies.

The y-axis label (Average ring-width anomaly) will be added

Fig. 5: Similar to Fig. 3, the y-axis label is missing. The x-axis label ("Years since event year") should be put under the two columns since we have a map at the upper-left corner that does not share such x-axis label.

The y-axis label (Average ring-width anomaly) will be added, and the x-axis label moved.

Figs. 6, S7, S8, S10: The x-axis label is missing.

The x-axis label will be added.

Figs. S2-S6: It seems that the legends are raw codes without any explanation in the caption, and it would be difficult to understand for people who's not familiar with these codes.

We propose that a table with site meta-data for each code is added to Supplementary Information (attached at the end of this document). The legend for Figures S2-S6 would then be updated to link to the table.

L285-287: The readers will wonder why it is the case, and a pointer to the specific discussion section is needed here.

Agreed.

Response by authors to Reviewer Comment 1

Northern Hemisphere high altitude/latitude chronologies predominantly used to determine the climatic effects of volcanic eruptions contain higher biological persistence than the chronologies we have used. In terms of the discussion in this paper, we would classify these trees as extreme stress tolerators. To illustrate, we refer to Table 9 in Cropper & Fritts (1981) which compares the ring width characteristics of arctic trees to more temperate Northern Hemisphere trees. The average first order autocorrelation of the series used to develop our temperature reconstructions is 0.53 (0.149-0.869) with standard deviation 0.15 compared to artic sites with average 0.62 (0.15 – 0.93) and standard deviation of 0.13.

L382: It seems that Figure 3 is the one to refer to, instead of Figure 2.

Yes, this needs to be updated to Figure 3.

L458-460: A pointer to Figure 7 is needed here.

Agreed.

L478: "MDX" is a typo.

Yes, thank you.
