

35 **ABSTRACT**

36 Here we present the experimental design and results from a new mid-Pliocene simulation using the  
37 latest version of the UK's physical climate model, HadGEM3-GC31-LL, conducted under the  
38 auspices of CMIP6/PMIP4/PlioMIP2. Although two other paleoclimate simulations have been  
39 recently run using this model, they both focused on more recent periods within the Quaternary and  
40 therefore this is the first time this version of the UK model has been run this far back in time. The  
41 mid-Pliocene Warm Period, ~3 Ma, is of particular interest because it represents a time period when  
42 the Earth was in equilibrium with CO<sub>2</sub> concentrations roughly equivalent to those of today, providing  
43 a possible analogue for current and future climate change.

44

45 The implementation of the Pliocene boundary conditions is firstly described in detail, based on the  
46 PRISM4 dataset, including CO<sub>2</sub>, ozone, orography, ice mask, lakes, vegetation fractions and  
47 vegetation functional types. These were incrementally added into the model, to change from a  
48 preindustrial setup to a Pliocene setup.

49

50 The results of the simulation are then presented, which are firstly compared with the model's pre-  
51 industrial simulation, secondly with previous versions of the same model and with available proxy  
52 data, and thirdly with all other models included in PlioMIP2. Firstly, the comparison with  
53 preindustrial suggests that the Pliocene simulation is consistent with current understanding and  
54 existing work, showing warmer and wetter conditions, and with the greatest warming occurring over  
55 high latitude and polar regions. The global mean surface air temperature anomaly at the end of the  
56 Pliocene simulation is 5.1°C, which is the 2<sup>nd</sup> highest of all models included in PlioMIP2 and is  
57 consistent with the fact that HadGEM3-GC31-LL has one of the highest Effective Climate  
58 Sensitivities of all CMIP6 models. Secondly, the comparison with previous generation models and  
59 with proxy data suggests a clear increase in global sea surface temperatures as the model has  
60 undergone development. Up to a certain level of warming, this results in a better agreement with  
61 available proxy data, and the "sweet spot" appears to be the previous CMIP5 generation of the model,  
62 HadGEM2-AO. The most recent simulation presented here, however, appears to show poorer  
63 agreement with the proxy data compared with HadGEM2, and may be overly sensitive to the Pliocene  
64 boundary conditions resulting in a climate that is too warm. Thirdly, the comparison with other  
65 models from PlioMIP2 further supports this conclusion, with HadGEM3-GC31-LL being one of the  
66 warmest and wettest models in all of PlioMIP2 and, if all the models are ordered according to  
67 agreement with proxy data, HadGEM3-GC31-LL ranks approximately halfway among them. A  
68 caveat to these results is the relatively short run length of the simulation, meaning the model is not in  
69 full equilibrium. Given the computational cost of the model it was not possible to run for longer; a  
70 Gregory plot analysis indicates that had it been allowed to come to full equilibrium, the final global  
71 mean surface temperature could have been approximately 1.5°C higher.

72 **1. INTRODUCTION**

73 Model simulations of past climate states are useful because, among other aspects, they allow us to  
74 interrogate the mechanisms that have caused past climate change (Haywood *et al.* 2020, Lunt *et al.*  
75 2021). They also give us a global picture of past climate variables (such as sea surface temperature,  
76 SST) that can only be reconstructed by geological data at specific locations, and of variables (such as  
77 upper atmospheric winds) that cannot be reconstructed by geological data at all. However, before  
78 models can be used in this way, it is important to validate them by comparing with geological data,  
79 where available, from the time periods of interest. Such model-data comparisons can also be useful  
80 for evaluating the model outside of the modern climate states that it was likely tuned to, thereby  
81 providing an independent assessment of the model that can be important for interpreting any future  
82 climate projections arising from the model (e.g. Zhu *et al.* 2020).

83

84 The mid-Pliocene Warm Period (mPWP, ~3 million years ago, hereafter referred to as the Pliocene) is  
85 an ideal climate state for such a model-data comparison because: i) there has recently been a  
86 concerted community effort to provide a synthesis of proxy SST reconstructions (McClymont *et al.*  
87 2020); ii) community-endorsed boundary conditions exist which can be used to configure climate  
88 model simulations (Haywood *et al.* 2016); and iii) there is a wealth of previous model  
89 intercomparison projects (MIPs), with which model simulations can be compared and contrasted, that  
90 have been carried out with these recent boundary conditions (PlioMIP2, Dowsett *et al.* 2016 and  
91 Haywood *et al.* 2020) and with previous versions of the boundary conditions (PlioMIP1, Haywood *et al.*  
92 *et al.* 2013). The Pliocene is also a relatively warm period compared to both preindustrial conditions  
93 and those of today, with comparable CO<sub>2</sub> levels to today (McClymont *et al.* 2020, Salzmann *et al.*  
94 2013), and so provides a climate state with similarities to those that might be expected in the future  
95 (Burke *et al.* 2018, Tierney *et al.* 2020).

96

97 PlioMIP2 was a community effort to carry out and analyse coordinated model simulations to explore  
98 mechanisms associated with Pliocene climate, and to evaluate multiple models with Pliocene proxy  
99 data. To date, 16 models have participated in PlioMIP2, all of which used boundary conditions from  
100 the US Geological Survey's PRISM4 (Pliocene Research, Interpretation and Synoptic Mapping v4;  
101 see Dowsett *et al.* 2016) and the results of this intercomparison and evaluation are described in  
102 Haywood *et al.* 2020 (hereafter abbreviated to H20). H20 first explored the large-scale features  
103 (global means, polar amplification and land-sea contrast) of temperature and precipitation in the  
104 simulations, finding a global ensemble mean warming of 3.2°C relative to preindustrial and a 7%  
105 increase in precipitation. There was a clear signal of polar amplification, but tropical zonal gradients  
106 remained largely unchanged compared with preindustrial. Compared with proxies from Foley and  
107 Dowsett (2019), the SSTs in the tropics were broadly consistent in the models and data, and in the  
108 Atlantic the polar amplification was better represented by the models compared with previous model-

109 data comparisons such as those from PlioMIP1. Recent studies using the PlioMIP2 ensemble have  
110 explored other aspects of the model simulations, such as ocean circulation (Zhang *et al.* 2021) and the  
111 African monsoon (Berntell *et al.*, in review). It is of interest to evaluate simulations from additional  
112 models as they become available, and that is what we do here, presenting results from a new model,  
113 HadGEM3-GC31-LL, for the Pliocene. This is of particular interest because HadGEM3-GC31-LL is  
114 a Coupled Model Intercomparison Project Phase 6 (CMIP6) “high Effective Climate Sensitivity  
115 (ECS)” model (Zelinka *et al.* 2020), with a climate sensitivity to CO<sub>2</sub> doubling of more than 5°C  
116 (Andrews *et al.* 2019). Only one other model in CMIP6, CanESM5, has a higher climate sensitivity  
117 (5.64°C compared with 5.55°C). HadGEM3-GC31-LL is also of interest because it represents the  
118 third generation of UK Met Office model that has participated in PlioMIP (Bragg *et al.* 2012, Tindall  
119 and Haywood 2020, Hunter *et al.* 2019), allowing us to assess how much, if any, progress has been  
120 made in simulating the Pliocene with the UK family of models.

121

122 In this paper we address 3 main questions:

- 123 1) What are the large-scale features of the Pliocene climate produced by HadGEM3-GC31-LL?
- 124 2) To what extent has the development of new boundary conditions and more complex models  
125 led to improvements in the simulation of the Pliocene by UK Met Office models?
- 126 3) How does HadGEM3-GC31-LL compare with other models participating in PlioMIP2?

127

128 Section 2 of this paper describes HadGEM3-GC31-LL, how the PlioMIP2 boundary conditions were  
129 implemented in the model, and the experimental design of the model. Section 3 presents the large-  
130 scale features of the Pliocene in HadGEM3-GC31-LL, and Section 4 compares the HadGEM3-GC31-  
131 LL simulation with proxy data and previous generations of the same UK model, and with other  
132 PlioMIP2 models.

133

## 134 2. MODEL AND EXPERIMENT DESIGN

### 135 2.1. Naming conventions and terminology

136 Consistent with CMIP nomenclature, when the simulation is spinning up towards atmospheric and  
137 oceanic equilibrium, with initially incomplete boundary conditions, it is referred to as the ‘Spin-up  
138 phase’ and is only briefly presented here. In contrast, once all required boundary conditions were  
139 implemented, the results themselves are taken from the end of the simulation, referred to here as the  
140 ‘Production run’. Here, results are based on the final 50-year climatology of this production run.  
141 Concerning geological intervals, the preindustrial and mid-Pliocene Warm Period are referred to as  
142 the PI and Pliocene, respectively. In contrast, concerning the model simulations using HadGEM3-  
143 GC31-LL, consistent with CMIP6 they are referred to as the *piControl* and *mPWP* simulations,  
144 respectively. We also make use of the naming convention of Haywood *et al.* 2016, hereafter  
145 abbreviated to H16), including the nomenclature Ex<sup>c</sup> (where c is the concentration of CO<sub>2</sub> in ppmv,

146 and  $x$  are any boundary conditions which are Pliocene as opposed to PI, which can be any or none of  
147  $o$  = orography,  $v$  = vegetation and  $i$  = ice sheets). So, for example,  $Eov^{500}$  would be an experiment  
148 using Pliocene orography and vegetation and with  $CO_2$  at 500 ppmv, but with preindustrial ice sheets.  
149

## 150 **2.2. Model description**

151 The model presented here is the Global Coupled (GC) 3.1 configuration of the UK's physical climate  
152 model, HadGEM3-GC31-LL, which is the "CMIP6-class" UK Met Office physical climate model.  
153 The *piControl* simulation for this model was conducted elsewhere as part of CMIP6, and is used here  
154 for comparative purposes; see Williams *et al.* (2017), Kuhlbrodt *et al.* (2018) and Menary *et al.*  
155 (2018) for further details on HadGEM3-GC31-LL and its *piControl* simulation. The *mPWP*  
156 simulation presented here was run with identical components to those used in other CMIP6/PMIP4  
157 simulations using this model, namely the *midHolocene* and *lig127k* simulations (Williams *et al.*  
158 2020). The full title for this configuration is HadGEM3-GC31-LL N96ORCA1 UM10.7 NEMO3.6  
159 (hereafter referred to as HadGEM3). The model was run using the Unified Model (UM), version  
160 10.7, and included the following components: i) Global Atmosphere (GA) version 7.1, with an N96  
161 atmospheric spatial resolution (approximately  $1.875^\circ$  longitude by  $1.25^\circ$  latitude) and 85 vertical  
162 levels; ii) NEMO ocean version 3.6, including Global Ocean (GO) version 6.0 (ORCA1), with an  
163 isotropic Mercator grid which, despite varying in both meridional and zonal directions, has an  
164 approximate spatial resolution of  $1^\circ$  by  $1^\circ$  and 75 vertical levels; iii) Global Sea Ice (GSI) version 8.0  
165 (GSI8.0); iv) Global Land (GL) version 7.0, comprising the Joint UK Land Environment Simulator  
166 (JULES); and v) the OASIS3 MCT coupler. All of the above individual components are summarised  
167 by Williams *et al.* (2017) and detailed individually by a suite of companion papers (see Walters *et al.*  
168 2017 for GA7 and GL7, Storkey *et al.* 2017 for GO6 and Ridley *et al.* 2017 for GSI8). A summary of  
169 the major changes in HadGEM3 and their impacts on the climate, relative to its most recent  
170 predecessor (HadGEM2), are given in Williams *et al.* (2020). Here, the *mPWP* simulation was run on  
171 NEXCS, which is a component of the Cray XC40 located at the UK Met Office. NEXCS is a  
172 partition of the UK Met Office's platform, Monsoon, on which the *piControl* simulation was run,  
173 thereby avoiding the potential caveat discussed in Williams *et al.* (2020) concerning different  
174 computing platforms.

175

176 Details of the other models discussed here, namely previous generations of the same UK Hadley  
177 Centre model and all of those included in PlioMIP2, are included in the Supplementary Material  
178 (Section 1).

179

## 180 **2.3. Full Pliocene experiment design**

181 For the most part, the *mPWP* simulation presented here follows the protocol given in H16, discussed  
182 below. The main difference is that we do not modify the land-sea mask (LSM), due to technical  
183 challenges of modifying the ocean LSM and coupling it to the atmosphere in this model.

184

### 185 **2.3.1. Greenhouse gas atmospheric concentrations, aerosol emissions and ozone**

186 Following H16, atmospheric CO<sub>2</sub> concentration was modified in the *mPWP* simulation, from 280 to  
187 400 ppmv. All other greenhouse gases, such as CH<sub>4</sub>, N<sub>2</sub>O and O<sub>2</sub>, were kept as in the *piControl*  
188 simulation. Likewise, aerosol emissions (e.g. organic- and black-carbon fossil fuels) and their  
189 resulting oxidants were kept as in the *piControl* simulation, consistent with previous paleoclimate  
190 simulations with this model (Williams *et al.* 2020).

191

192 Under strong surface warming, the thermal tropopause rises. In simulations with prescribed ozone  
193 concentration it is important that the thermal tropopause remains below the ozone tropopause, in order  
194 to avoid unphysical feedbacks associated with increasing cold point temperature (see, for example,  
195 Hardiman *et al.* 2019). For this reason, ozone from the *IpctCO<sub>2</sub>* simulation of the UK Earth System  
196 Model (UKESM1, see Sellar *et al.* 2019), in which CO<sub>2</sub> concentrations are increased relative to 1850  
197 levels at 1% per year, was prescribed here. UKESM1 uses the same physical climate configuration as  
198 HadGEM3, but interactively simulates ozone chemistry. The ozone was taken from a 10-year period  
199 of this UKESM1 simulation (years 51-60), during which the mean surface temperature was  
200 approximately 2°C warmer than the *piControl* simulation. The value of 2°C was chosen as a  
201 compromise between raising the ozone tropopause enough to avoid inconsistency with the thermal  
202 tropopause, without introducing significant changes in ozone forcing relative to the *piControl*. The  
203 impact of the ozone modification could be explored in future work, for example by using an ozone  
204 profile from a UKESM1 simulation with a higher mean surface temperature (more consistent with the  
205 HadGEM3 Pliocene warming, see Section 3), or by using the methodology outlined in Hardiman *et*  
206 *al.* (2019), which was used for the CMIP6 Shared Socioeconomic Pathway (SSP) scenario simulations  
207 with HadGEM3.

208

### 209 **2.3.2. Changes to boundary and initial conditions**

#### 210 **2.3.2.1. Palaeogeography (including land-sea mask, orography and bathymetry)**

211 The *mPWP* simulation used an identical LSM to the *piControl* simulation which, if necessary, is  
212 allowed under the experimental design laid out in H16. This differs from both the standard and  
213 enhanced LSMs provided by H16 (accessible, with all other required boundary conditions, from the  
214 US Geological Survey's PlioMIP2 website, [http://geology.er.usgs.gov/egpsc/prism/7\\_pliomip2.html](http://geology.er.usgs.gov/egpsc/prism/7_pliomip2.html)),  
215 in that in both of these the gateways in the Bering Sea, the Canadian Archipelago and Hudson Bay are  
216 closed, whereas in the HadGEM3 simulations only the Canadian Archipelago/Hudson Bay gateway is

217 closed; the Bering Strait is open (see Supplementary Material, Fig. S1). Likewise, the bathymetry  
218 used here is also identical to the *piControl* simulation, for the same reasons.

219

220 The orography used in the *mPWP* simulation, however, does follow the protocol of H16. Here, an  
221 anomaly is firstly created by subtracting the PRISM4 modern orography from the PRISM4 Pliocene  
222 orography and then, after having been re-gridded to the model's own resolution, adding this to the  
223 model's existing orography (see Section 2.3.2 in H16). The results are shown in Figure 1, where the  
224 PRISM4 anomaly shows the largest changes are occurring over Greenland and Antarctica, with  
225 smaller changes over the Himalayas, North America and Africa (Fig. 1a). When added to  
226 HadGEM3's existing orography (Fig. 1b), the changes result most obviously in a lowering of  
227 orography over Greenland, western and eastern Antarctica, and a raising of orography over central  
228 Antarctica (Fig. 1c). Due to an early model instability relating to the steep orographic gradients in  
229 western Antarctica, this region was smoothed in the final simulation (Fig. 1c).

230

231 Figure 1 - Changes to topography in HadGEM3 *mPWP* simulation. a) PRISM4 anomaly; b) Original field used in  
232 HadGEM3 *piControl*; c) New field used in HadGEM3 *mPWP*, with smoothed topography over western Antarctica (final  
233 version, used in simulation)

234

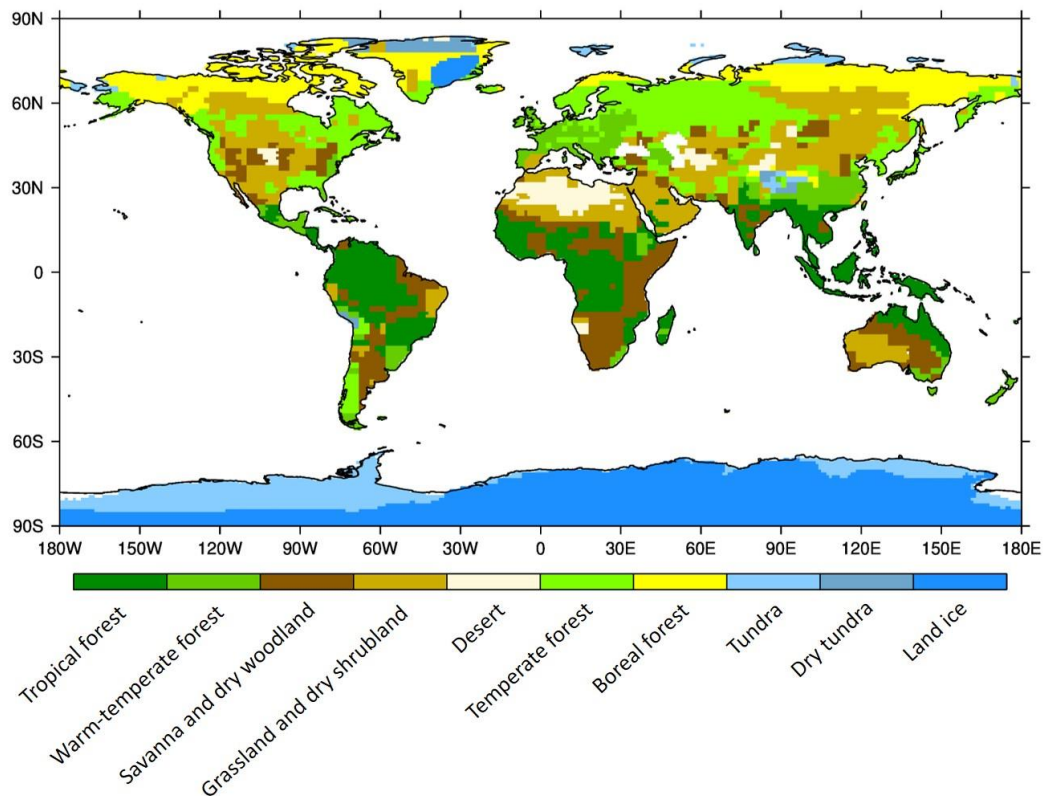

### 235 2.3.2.2. *Vegetation fractions (including urban, lakes and ice)*

236 As part of its GL configuration, both the *piControl* and *mPWP* simulations used the community land  
237 surface model (JULES; see Best *et al.* 2011, Clark *et al.* 2011, Walters *et al.* 2019). In this land  
238 surface model, sub-gridscale heterogeneity is represented by a tile approach (Essery *et al.* 2003), in

239 which each grid box over land is divided into five vegetated plant functional types (PFTs): broadleaf  
240 trees (BLT), needle-leaved trees (NLT), temperate C3 grass, tropical C4 grass and shrubs. In addition  
241 to these, there are four non-vegetated PFTs: urban areas, inland water (or lakes), bare soil and land  
242 ice. This division of grid box into PFTs is consistent with both of the model's predecessors (see  
243 Supplementary Material). With the exception of the urban tile, which was kept as PI to be consistent  
244 with previous paleoclimate simulations with this model (Williams *et al.* 2020), all of these PFTs were  
245 modified in the *mPWP* simulation.

246

247 The US Geological Survey's PRISM4 (Dowsett *et al.* 2016) vegetation reconstruction from Salzmann  
248 *et al.* (2008) was used, provided as a megabiome reconstruction in PlioMIP2 (H16). This can be seen  
249 in Figure 2, where there are ten listed megabiomes corresponding to those used in Harrison and  
250 Prentice 2003: tropical forest, warm-temperate forest, savanna and dry woodland, grassland and dry  
251 shrubland, desert, temperate forest, boreal forest, tundra, dry tundra and land ice.

252

253 Figure 2 - Ten megabiomes from PlioMIP2 used create the nine PFTs used in HadGEM3 *mPWP* simulation

254

255

256

257

258 In order to translate the megabiomes from PRISM into the PFTs used by the model, a lookup table  
259 was therefore required. Minimum and maximum bounds for each megabiome were firstly obtained,  
260 based on values from Crucifix *et al.* 2005, and then estimates were made for each PFT within these  
261 bounds by mapping the preindustrial megabiomes onto the preindustrial PFT in HadGEM3; the  
262 resulting lookup table is shown in the Supplementary Material (Table S1). In this table, for example,  
263 each land grid point with the megabiome “Tropical forest” is divided amongst the model PFTs as 92%  
264 BLT, 5% bare soil, 2% tropical C4 grasses and 1% shrubs. The resulting 9 PFTs used in the *mPWP*  
265 simulation, as well as those from the original *piControl*, are shown in Figure 3. The largest fractional  
266 increases, relative to the *piControl*, occur for broadleaf trees and needleleaf trees (18% and 5%,  
267 respectively; Fig. 3a and b) and the largest decreases occur for temperate C3 grass and land ice (15%  
268 and 5%, respectively; Fig. 3c and i). In regions where there is no obvious match between the model’s  
269 PFTs and the megabiomes, such as over western Antarctica (specified as tundra in the PRISM data), a  
270 closest match was provided; in this case, a mix of bare soil and shrubs.

271

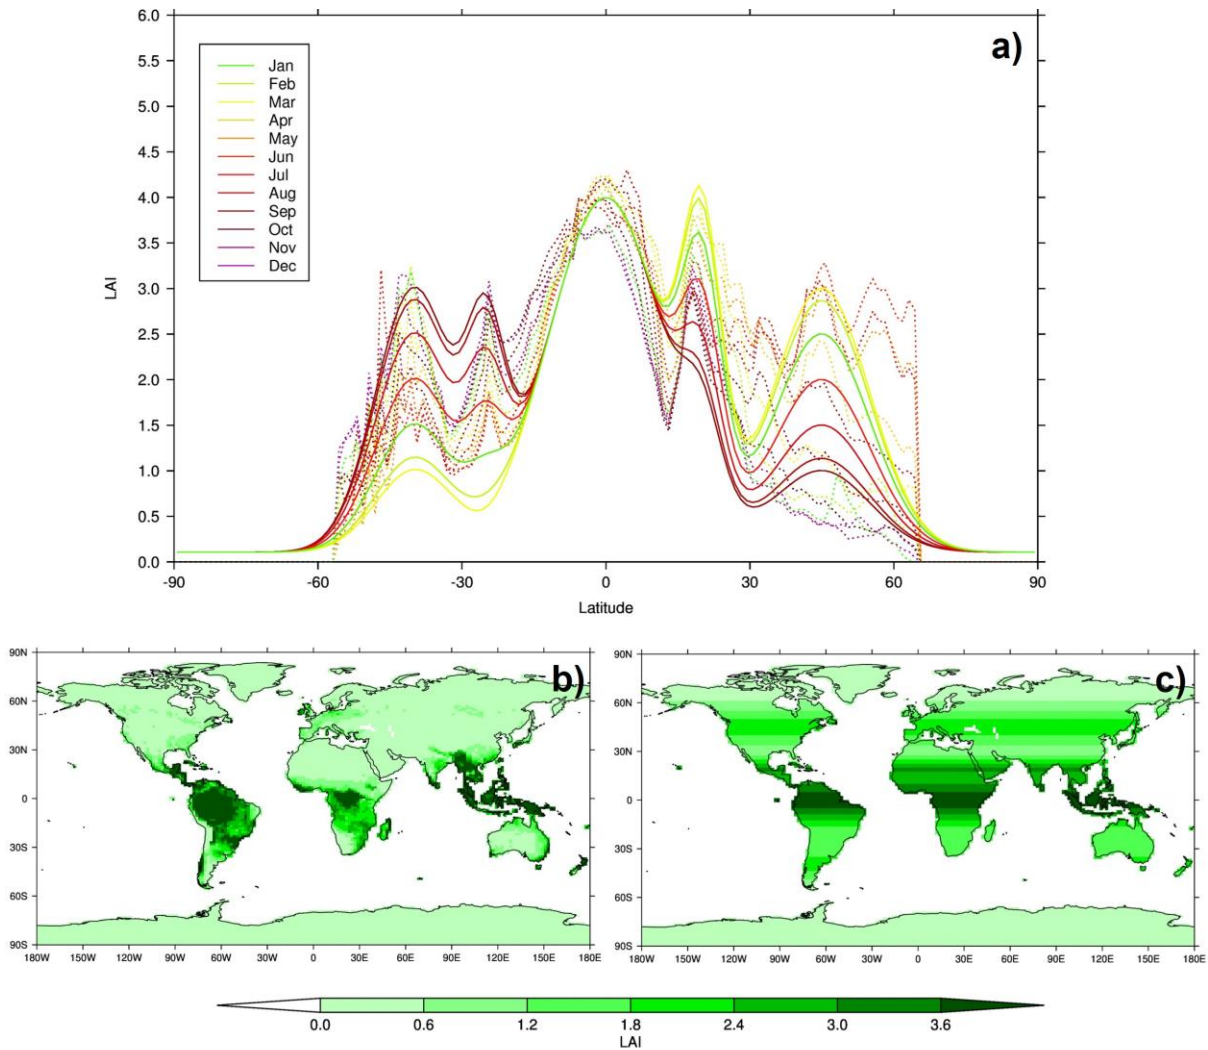

272 Figure 3 - Nine PFTs used in HadGEM3. Top half: *piControl* simulation, bottom half: *mPWP* simulation. Values in  
 273 brackets show global mean differences (*mPWP* - *piControl*), expressed as a percentage. a) broadleaf trees (18%); b) needle-  
 274 leaved trees (5%); c) temperate C3 grass (-15%); d) tropical C4 grass (6%); e) shrubs (3%); f) urban areas (no change); g)  
 275 inland water (1%); h) bare soil (-12%); i) land ice (-5%)

276

277

### 278 2.3.2.3. *Vegetation functional types*

279 Alongside the vegetation fractions, both the *piControl* and *mPWP* simulations included two monthly-  
280 varying vegetation functional types, namely leaf area index (LAI) and canopy height, both of which  
281 are associated with each of the five vegetated PFTs. Given that no information was available from the  
282 PRISM vegetation reconstruction concerning these fields, two methods were used to create Pliocene  
283 LAI and canopy height. For LAI, a seasonally and latitudinally varying function was created from the  
284 zonal means of the *piControl* (Figure 4), and used to build a new field for the Pliocene, for each  
285 month and each PFT (see Fig. 4b and c for an example of the original *piControl* and the Pliocene  
286 newly-created field, respectively, both showing LAI for BLT during January). This is because, in the  
287 *piControl*, LAI varies both in time (i.e. seasonally) and space. Note that although LAI does go to zero  
288 in the *piControl*, this was not allowed in the *mPWP* simulation because the Pliocene does have some  
289 vegetation at high latitudes (see Figure 3); these functions were therefore increased by  $x$  (where  $x =$   
290 the mean of the ten grid points containing the lowest LAI), such that there is never zero LAI. In  
291 contrast, canopy height in the *piControl* does not vary monthly, and has little variation spatially,  
292 therefore canopy height in the *mPWP* simulation is set to the global mean of the *piControl* (see  
293 Supplementary Material Fig. S2).

294

295 Figure 4 – LAI used in HadGEM3, for an example PFT (broadleaf trees). a) Function used to create LAI, where dashed  
 296 lines show zonal mean from *piControl* simulation and solid lines show seasonally and latitudinally varying function used in  
 297 the *mPWP* simulation; b) Example of functional types (broadleaf trees, January) used in *piControl* simulation; c) same as b)  
 298 but for the *mPWP* simulation/  
 299

300

### 300 2.3.2.3. Soil properties and snow depth

301 Under newly-created land ice based on the new Pliocene ice mask (i.e. in regions where there is no ice  
 302 in the *piControl* but ice the *mPWP* simulation), soil parameters, soil dust properties and snow depth  
 303 were set to be appropriate values for existing ice regions i.e. whatever these values are under ice in the  
 304 *piControl* simulation are applied to the newly-created ice regions in the *mPWP* simulation.  
 305

306

307 Conversely, and more importantly in this context (as the Pliocene represents an overall removal of  
 308 ice), under newly-exposed land based on the new Pliocene ice mask (i.e. in regions where there is ice  
 309 in the *piControl* but no ice in the *mPWP* simulation, primarily over Greenland and western  
 310 Antarctica), the dominant vegetation fractions in these regions were firstly identified from the newly-  
 310 created Pliocene vegetation. In this case, the dominant fractions were 40% shrubs and 60% bare soil.

311 Then, grid points containing this vegetation balance in the *piControl* were identified, and the soil  
312 parameters, soil dust properties and snow depth values at these points were averaged. This average  
313 value, for each of the above fields, was lastly inserted back into the *mPWP* simulation's newly-  
314 exposed grid points; it is acknowledged that this introduces new dust emissions source regions, which  
315 may well impact the resulting Pliocene climate state.

316

#### 317 **2.3.2.4. Initial conditions**

318 Oceanic initial conditions, such as ocean temperature and salinity, were derived from the mean  
319 equilibrium state of the *piControl* simulation. Some atmospheric initial conditions, such as those  
320 relating to the land surface (e.g. soil moisture and soil temperature at four levels of depth), used the  
321 same method as that applied to soil properties. These fields contain monthly varying values, therefore  
322 appropriate timings were considered e.g. if the majority of grid points with the above balance were in  
323 the Northern Hemisphere, then initial conditions during Northern Hemisphere summer were used for  
324 newly-exposed regions in Greenland (and likewise during Southern Hemisphere summer for newly-  
325 exposed regions in Antarctica). For the soil temperature field and particularly at upper levels, this  
326 process resulted in sharp temperature gradients across western Antarctica, therefore the field was  
327 spatially smoothed so that the gradients were more consistent with those in the *piControl*. Examples  
328 of the above soil-related fields are shown in Figure 5 for an example month and vertical level. A  
329 complete list of the soil parameters and soil dust properties, and how each were changed relative to  
330 the *piControl*, are shown in the Supplementary Material (Fig. S3 and Fig. S4, respectively).

331

332 Outside of the ice regions (i.e. outside Greenland and Antarctica), in the *mPWP* simulation the above  
333 soil-related fields were kept identical as in the *piControl*.

334

335 Figure 5 – Example of soil-related fields used in HadGEM3. Left-hand column: *piControl* simulation, right-hand column:  
 336 *mPWP* simulation. First row: Soil parameters (example shows Volumetric soil moisture content at wilting point); Second

339

### 340 2.3.3. Changes to input parameters

341 A small number of model input parameters were changed in the *mPWP* simulation, to make the model  
 342 more stable under the Pliocene boundary conditions. Firstly a parameter governing the implicit solver  
 343 for unstable atmospheric boundary layers was increased, and secondly three parameters for the  
 344 treatment of canopy snow were made consistent between BLT and NLT. The same parameter  
 345 changes will be included in the subsequent version of the physical model (GC4), in order to address  
 346 occasional model failures which were seen following the release of GC3.1. They will be described in

347 more detail in a GC4 model documentation paper, however testing of those changes for GC4 has  
348 found that they have no detectable impact on model climatology.

349

#### 350 **2.4. Modified *piControl* simulation**

351 Given that the official CMIP6 *piControl* simulation did not use the aforementioned model input  
352 parameter changes, a slightly modified version of this simulation was re-run (simulation ID: u-bq637),  
353 identical to the *piControl* other than including the parameter changes outlined in Section 2.3.3  
354 (hereafter referred to as the *piControl\_mod* simulation). This was run for 200 years, and the last 50-  
355 year climatology is considered here in Sections 3 and 4.

356

### 357 **3. LARGE-SCALE FEATURES OF HADGEM3**

#### 358 **3.1. Spin-up phase**

359 Consistent with other paleoclimate model experiments, the simulation should be run for as long as  
360 possible to allow the model to reach a state of equilibrium, before the climatology is calculated over  
361 the last 30, 50 or 100 years (Lunt *et al.* 2017). With this model, however, running for thousands of  
362 years (especially important in obtaining oceanic equilibrium) was unfeasible given time and resource  
363 constraints. By the end of the simulation, therefore, there was a total of 576 years for the *mPWP*  
364 simulation, 526 of which are considered spin-up and 50 of which form the final climatologies; this is  
365 approximately consistent with the 652 years of spin-up used by Menary *et al.* (2018).

366

##### 367 **3.1.1. Evolution of *mPWP* simulation**

368 The HadGEM3 *mPWP* simulation was run in multiple parts, each starting from the endpoint of the  
369 last, and each introducing additional boundary conditions so as to gradually move from PI conditions  
370 to full Pliocene conditions. The *mPWP* simulation was started from the endpoint of the CMIP6  
371 *piControl* simulation, specifically the last part of its spin-up phase (u-aq853), consistent with other  
372 CMIP6 HadGEM3 paleoclimate simulations such as those of the mid-Holocene and Last Interglacial  
373 periods (see Williams *et al.* 2020). The evolution of the *mPWP* simulation is shown in Figure 6,  
374 where each stage is labelled and the resulting impact on the global mean 1.5 m air temperature is  
375 shown. The first part of the *mPWP* simulation (u-bq448) is a straight copy of the CMIP6 *piControl*  
376 production run (u-ar766), with no modifications other than increasing the atmospheric CO<sub>2</sub> to 400  
377 ppmv; identical, therefore, to an E<sup>400</sup> experiment following the naming convention of H16. This ran  
378 for ~20 model years, before branching off to a new suite (u-br005) and introducing atmospheric ozone  
379 appropriate for Pliocene conditions and Pliocene orography (see Section 2.3.1 and 2.3.2,  
380 respectively). This ran for ~60 model years, before branching off to a new suite (u-br871) and  
381 introducing a Pliocene-appropriate ice mask along with appropriate values for soil parameters, soil  
382 dust, soil moisture, soil temperatures and snow depth over these newly created ice regions (see  
383 Section 2.3.2); this, therefore would be the Eoi<sup>400</sup> experiment following the naming convention of

384 H16. It should be noted, however, that at this stage this naming convention is not strictly consistent  
 385 with that used by H16, because they specify that orography, lakes and soils should be modified in  
 386 unison, and therefore *o* signifies changes to orography, bathymetry, land-sea mask, lakes and soils  
 387 together. In contrast, at this stage of the simulation, most boundary conditions are consistent with the  
 388 experimental design of H16, except vegetation, soils in non-ice regions and lakes. This ran for ~280  
 389 model years (during which time the task of creating appropriate Pliocene vegetation was completed),  
 390 before branching off to a new suite (u-bv241) and introducing a minor parameter change to allow  
 391 inclusion of the Pliocene vegetation (see Section 2.3.3), as well as the full Pliocene vegetation  
 392 fractions. This ran for a further ~60 years, to check the stability of the model in response to the  
 393 vegetation change, before branching off to a new and final suite (u-bv963), in which the full Pliocene  
 394 vegetation functional types were introduced. This ran for ~150 years, with the final climatology  
 395 (presented here in Section 3 and 4) being taken from the last 50 years i.e. allowing a 100-year buffer  
 396 between the final update to the model and the actual results.

397  
 398 Figure 6 – Annual global mean 1.5 m air temperature from the HadGEM3 *mPWP* spin-up phase and production run, as well  
 399 as the CMIP6 *piControl* and the *piControl\_mod*. Labels show introduction of each new Pliocene element. Climatologies  
 400 discussed here are taken from final 50 years of each simulation (shown by shaded boxes). See Williams *et al.* (2020) for the  
 401 *piControl* spin-up phase that preceded these simulations.

402  
 403 As well as the various stages of the *mPWP* simulation, Figure 6 also shows timeseries from the  
 404 official ~500 year CMIP6 *piControl* simulation (Kuhlbrodt *et al.* 2018 and Menary *et al.* 2018) and  
 405 the 200 year *piControl\_mod* conducted here, and Figure S7 shows climatologies of 1.5 m temperature  
 406 and surface precipitation calculated over the last 50 years of each simulation. As the figures show,  
 407 there is little or no difference between the two PI simulations (also suggested above in Section 2.3.3);

408 using temperature as an example, over the last 50 years of the simulations there is a mean of 13.79°C  
 409 and 13.97°C for the *piControl* and *piControl\_mod* respectively, and a standard deviation of 0.13°C for  
 410 both, further confirming the negligible impact of the model parameter change in the model  
 411 climatology.

412

413 **3.1.2. Atmospheric and oceanic equilibrium of the *mPWP* simulation**

414 Concerning atmospheric equilibrium, Table 1 shows summary statistics for annual global mean 1.5 m  
 415 air temperature and net top of atmosphere (TOA) radiation from the last 50 years of the *mPWP*  
 416 simulation, compared to both the *piControl* and *piControl\_mod* simulations; see Figure 6 for the  
 417 entire timeseries of Pliocene 1.5 m air temperature, and Figure S5 in the Supplementary Material for  
 418 the TOA radiation equivalent.

Variable	<i>piControl</i>	<i>piControl_mod</i>	<i>mPWP</i>
<b>1.5m air temperature trends</b> (°C century <sup>-1</sup> )	0.51	-0.47	0.34
<b>TOA radiation trends (W m<sup>2</sup></b> century <sup>-1</sup> )	0.02	-0.2	-0.17
<b>Mean TOA radiation (W m<sup>2</sup>)</b>	0.18	0.21	0.88
<b>Global ocean volume-mean</b> <b>temperature trends (°C</b> century <sup>-1</sup> )	0.03	0.04	0.21
<b>Global ocean volume-mean</b> <b>salinity trends (psu century<sup>-1</sup>)</b>	0.0004	-0.0002	-0.004

419

420 Table 1 - Centennial trends (calculated via a linear regression) and climatology over the last 50 years of the simulations. A  
 421 positive TOA imbalance indicates a net loss of energy from the Earth System

422

423 Although the *mPWP* simulation is clearly warming considerably during the ~500 year run (and  
 424 especially when the Pliocene vegetation fraction is introduced), with trends of 0.77°C century<sup>-1</sup>, it  
 425 levels off over the final 50 years, with trends of 0.34°C century<sup>-1</sup> (Table 1). These values are higher  
 426 than those considered by some (e.g. Menary *et al.* 2018) to be acceptable for equilibrium, however  
 427 given time and resource constraints it was not possible to run the simulation further. The spatial  
 428 patterns of these trends, shown in Figure S6 in the Supplementary Material, shows the majority of the  
 429 warming occurring over high latitude regions in both Hemispheres, related to the removal of the ice  
 430 sheets and sea ice loss. By the end of the *mPWP* simulation, the mean TOA radiation balance is 0.88  
 431 W m<sup>-2</sup>, significantly higher than either of the PI simulations suggesting that the *mPWP* simulation is  
 432 not yet in full atmospheric equilibrium. This TOA imbalance is reducing at a rate of 0.17 W m<sup>-2</sup>

433 century<sup>-1</sup> at the end of the simulation. A brief discussion of how the HadGEM3 *mPWP* simulation's  
434 atmospheric equilibrium compares to that of the other Hadley Centre models presented here  
435 (introduced in Section 4) is given in the Supplementary Material (see Section 2 and Table S2).

436

437 When the *mPWP* simulation was stopped, the global annual mean 1.5 m temperature was  
438 approximately 19°C (Fig. 6). A Gregory plot (Gregory *et al.* 2004) of the evolution of TOA energy  
439 imbalance and surface temperature can indicate how much more warming the model may have  
440 experienced if it had been run to full equilibrium. The results of this analysis suggest the model  
441 would come to equilibrium ~1.5°C higher (see Supplementary Material, Fig. S8), at 20.5°C i.e. an  
442 anomaly relative to preindustrial of 6.6°C. This is the case when the extrapolation is carried out on  
443 either of the final two parts of the simulation (in red and in purple in Fig. S8), suggesting that the  
444 introduction of the Pliocene vegetation functional types is not having a great impact on the final  
445 global mean temperature. However, this analysis is associated with some uncertainty, related to the  
446 interannual variability in temperature and TOA energy imbalance, and to the fact that the linear  
447 extrapolation may not be appropriate if the feedbacks vary non-linearly (e.g. Knutti *et al.* 2015).

448

449 As an example of oceanic equilibrium, Table 1 also shows summary statistics for volume integral  
450 annual global mean ocean temperature and salinity from the end of the *mPWP* simulation, compared  
451 to both the *piControl* and *piControl\_mod* simulations; see Figure S9 in the Supplementary Material  
452 for the Pliocene timeseries. Ocean temperature is steadily increasing throughout the *mPWP*  
453 simulation, and likewise ocean salinity is steadily decreasing (Fig. S9). Freshwater fluxes to the  
454 ocean representing iceberg calving and ice sheet basal melt are calibrated for the *piControl*, as  
455 described in Sellar *et al.* (2020). These fluxes are calibrated to match the ice sheet surface mass  
456 balance (SMB) expected in the *piControl*, so that salinity drift is minimised. The Pliocene SMB is  
457 smaller than that in the *piControl*, and hence net flux of water to the ocean is positive, leading to the  
458 salinity drift. If compute resources allowed for a much longer Pliocene simulation, this ocean flux  
459 could be calibrated to Pliocene SMB once the temperature and SMB had stabilised, or calculated  
460 iteratively. The long-term trends, Table 1, provide similar conclusions to those from the atmospheric  
461 trends, with for example centennial temperature trends of 0.21°C century<sup>-1</sup> being much higher than the  
462 PI simulations (0.03°C century<sup>-1</sup> and 0.04°C century<sup>-1</sup> for the *piControl* and *piControl\_mod*,  
463 respectively). Although these values again do not meet the criteria of Menary *et al.* (2018) for  
464 oceanic equilibrium, given the aforementioned computational cost of this model it was not possible to  
465 run the simulations further; this is even more true in the ocean, which would require many thousands  
466 of years of model simulation to reach equilibrium. This compromise has been equally necessary for  
467 other computationally expensive paleoclimate simulations (e.g. Williams *et al.* 2020).

468

469 **3.2. Simulation comparison: *mPWP* versus *piControl\_mod* climatologies**

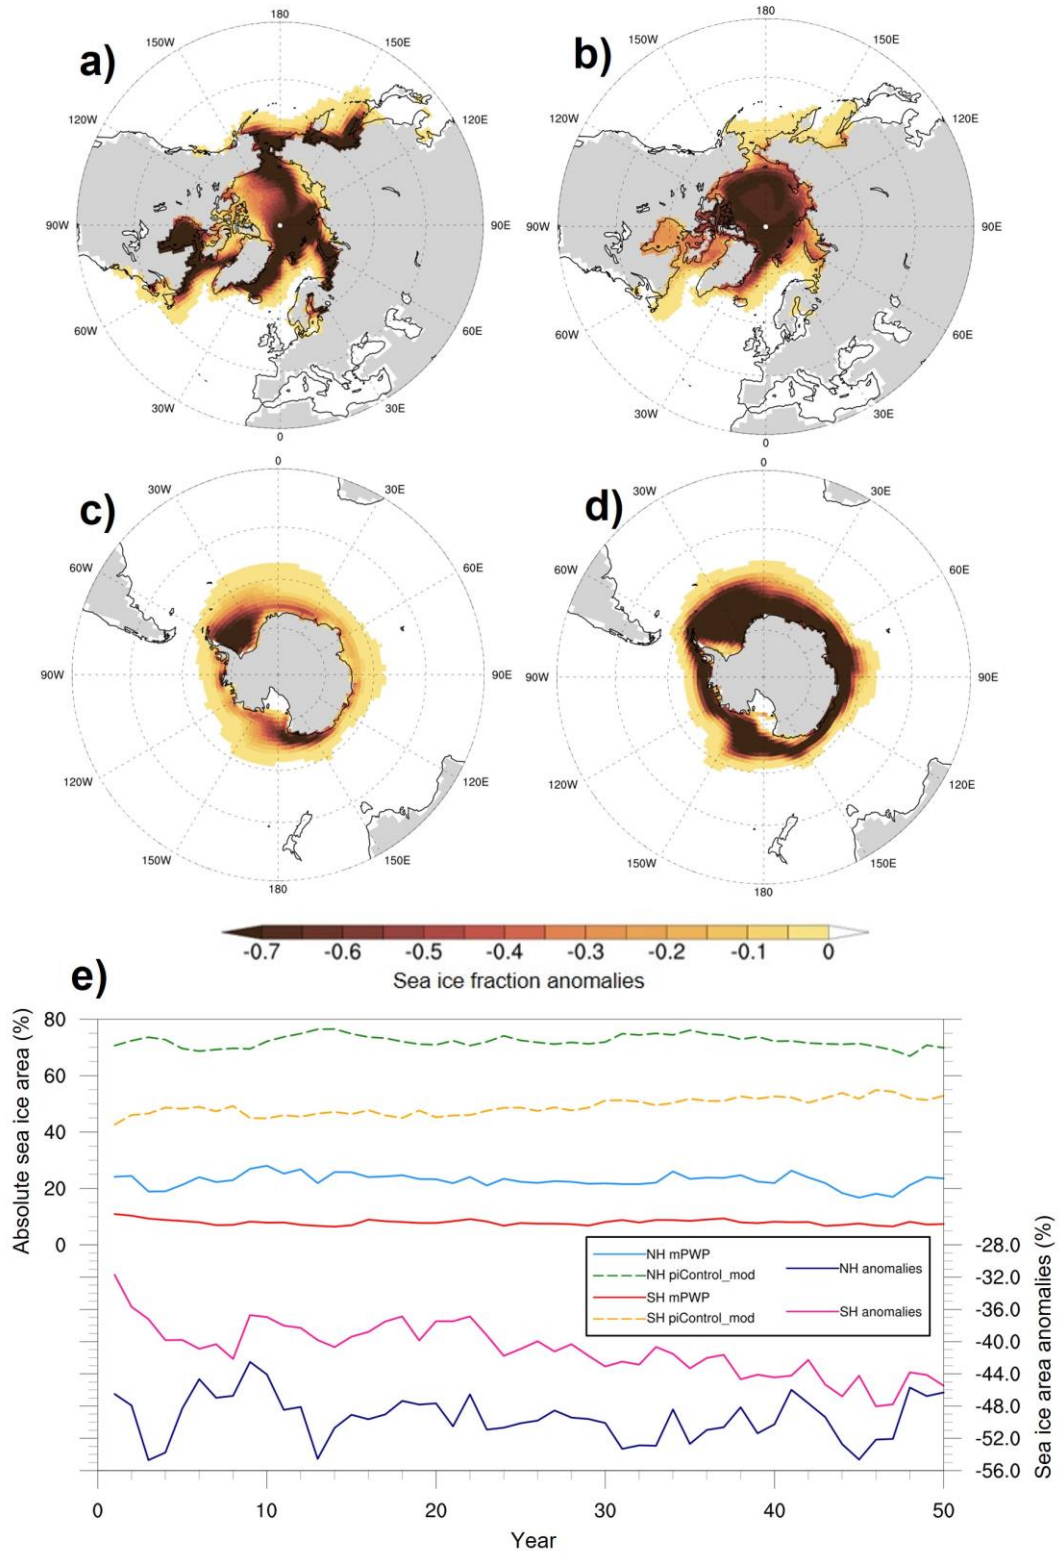

470 Here the focus is on mean differences between the HadGEM3 *mPWP* simulation and its  
471 corresponding modified PI simulation, *piControl\_mod* (Section 2.4). All of the following discussion  
472 and figures relate to climatologies calculated over the last 50 years of the simulations, and all are  
473 anomalies i.e. Pliocene - PI. Annual and seasonal mean summer/winter 1.5 m air temperature  
474 (hereafter referred to as near-surface air temperature, SAT) anomalies are shown in Figure 7. The  
475 annual global mean SAT anomaly for this 50-year climatology is 5.1°C. Warming relative to the PI is  
476 evident throughout the year and globally, but more so over: i) landmasses (6.8°C and 4.5°C for the  
477 annual mean SAT over land and ocean, respectively); ii) the Northern Hemisphere (8.5°C and 6.3°C  
478 for annual mean SAT in the Northern and Southern Hemisphere extratropics (>45°), respectively).  
479 Warming is also evident over high latitudes (>60°) of both hemispheres (10.9°C and 8.5°C for the  
480 Northern and Southern Hemisphere, respectively, and exceeding 12°C in some places). These  
481 particular metrics were chosen to be consistent with those used by H20 (see Section 4.2). Over the  
482 tropics (20°N-20°S) the amount of warming is less than at higher latitudes, but the Pliocene is still  
483 much warmer than the PI with annual mean SAT anomalies of 4.6°C and 3.7°C when averaged over  
484 tropical land and ocean, respectively. This global and regional warming is consistent with, albeit  
485 slightly warmer than, other work, namely the results from PlioMIP1 (Haywood *et al.* 2013) and  
486 PlioMIP2 (see Section 4.2). The majority of the annual mean warming (Fig. 7a) in Northern  
487 Hemisphere high latitudes is accounted for during that hemisphere's winter (December-February,  
488 DJF) with a mean warming of 15°C (Fig. 7b), and likewise the majority of the annual mean warming  
489 in Southern Hemisphere high latitudes is accounted for during that hemisphere's winter (June-August,  
490 JJA) with a mean warming of 10.6°C (Fig. 7c). If the entire hemisphere, rather than >60°, is  
491 considered, then this greater winter contribution to the annual mean is still true, although less so (e.g.  
492 5.6°C, 6.1°C and 5.4°C for the annual, DJF and JJA means respectively in the Northern Hemisphere).  
493

494 The regions of polar SAT increases, and seasonal variation, are likely explained by the changes in sea  
495 ice, shown in Figure 8 (for the absolute values in sea ice fraction, see Fig. S10 in the Supplementary  
496 Material). Reductions in sea ice are shown throughout the year in both hemispheres, consistent with  
497 previous work (e.g. Cronin *et al.* 1993, Howell *et al.* 2016, Moran *et al.* 2006, Polyak *et al.* 2010).  
498 Here, although a reduction in sea ice (of up to 70%) is evident throughout the year in either  
499 hemisphere, at the seasonal timescale the largest loss (exceeding 70% in some places, such as the  
500 polar Arctic and Antarctic) is seen during each hemisphere's winter (Fig. 8a and 8d). The  
501 regions/timings of maximum warming (Fig. 7b-c) correspond well to the regions/timings of maximum  
502 sea ice loss, implying a role for the sea ice-albedo feedback. When sea ice area is averaged over each  
503 hemisphere (Fig. 8e), the Northern Hemisphere is clearly losing more sea ice in the *mPWP* simulation  
504 (relative to the *piControl\_mod*) than the Southern Hemisphere. However the amount of loss in the  
505 Southern Hemisphere is steadily increasing during the last 50 years of the *mPWP* simulation,

506 suggesting that had the model been allowed to run to full equilibrium, the difference between the  
 507 hemispheres would be reduced.

508

509 Figure 7 – 1.5 m air temperature climatology differences ( $mPWP - piControl\_mod$ ) from HadGEM3. a) Annual; b) DJF; c)  
 510 JJA

511

512 Figure 8 – Sea ice fraction climatology differences ( $mPWP - piControl\_mod$ ) from HadGEM3: a) Northern Hemisphere  
513 DJF, b) Northern Hemisphere JJA, c) Southern Hemisphere DJF, d) Southern Hemisphere JJA, e) Mean sea ice area (both  
514 absolute values and differences) averaged over either hemisphere

515

516 Annual and seasonal mean surface daily precipitation anomalies are shown in Figure 9. The annual  
517 global mean precipitation anomaly for this 50-year climatology is  $0.34 \text{ mm day}^{-1}$ . In addition to the  
518 precipitation increases at high latitudes at the annual timescale (Fig. 9a), which are again mostly  
519 accounted for by changes during the Northern and Southern Hemisphere's winter (Fig. 9b and c,  
520 respectively), the largest change relative to the PI is a northward displacement of the ITCZ. All  
521 timescales are showing wetter conditions over oceans to the North of the equator and drier conditions  
522 over oceans to the South of the equator. This is similar to work by Li *et al.* (2018), who suggested a  
523 poleward movement of Northern Hemisphere monsoon precipitation in PlioMIP1. There is also a  
524 noticeable enhancement of monsoon systems such as the East Asian and West African monsoon,  
525 consistent with previous work (e.g. Zhang *et al.* 2013, 2016). In some places, these changes exceed  
526  $\sim 2 \text{ mm day}^{-1}$ , geographically consistent with (albeit again much higher than) other work, such as the  
527 multi-model ensemble mean (MME) from PlioMIP2 models where increases rarely exceed  $\sim 1.2 \text{ mm}$   
528  $\text{day}^{-1}$  (see Section 4.2). These changes, and indeed the temperature changes over Northern  
529 Hemisphere landmasses, may be associated with changes to the total cloud cover, shown in Figure 10.  
530 Although the changes are small at the annual timescale (Fig. 10a), during Northern Hemisphere  
531 winter (Fig. 10b) there is a noticeable increase in cloud cover (of  $\sim 10\%$ ) over high latitude regions,  
532 corresponding to the increases in precipitation. Likewise, during Northern Hemisphere summer (Fig.  
533 10c) there is a large reduction (over 20% in places) in cloud cover, especially over Northern  
534 Hemisphere landmasses; these regions, such as Europe and Northern Asia, correspond well to the  
535 areas of decreased precipitation and increased temperature.

 542

543 **4. COMPARISON OF HADGEM3 WITH OTHER MODELS AND PROXY DATA**

544 **4.1. Model-model and model-data comparison: Different generations of UK model versus proxy**  
 545 **data**

546 Here the focus is on mean SST differences between different generations of the UK’s physical climate  
 547 model, starting with three Pliocene simulations using the original fully-coupled climate model  
 548 HadCM3, then a simulation from the more recent HadGEM2 and finally the *mPWP* simulation from  
 549 HadGEM3. See Supplementary Material for details of these older models. For HadCM3, three  
 550 separate Pliocene simulations (and corresponding PIs) are used; the first two were conducted by Lunt  
 551 *et al.* (2011) and Bragg *et al.* (2012), and are referred to as HadCM3-PRISM2 and HadCM3-  
 552 PlioMIP1, respectively (see Table 2). This is to distinguish them from a third version of the same  
 553 model included in PlioMIP2, referred to here as HadCM3-PlioMIP2.

Model	Model name here	MIP	Boundary conditions	Reference
HadCM3	HadCM3-PRISM2	-	PRISM2	Lunt <i>et al.</i> 2011
HadCM3	HadCM3-PlioMIP1	PlioMIP1	PRISM3	Bragg <i>et al.</i> 2012
HadCM3	HadCM3-PlioMIP2	PlioMIP2	PRISM4	Hunter <i>et al.</i> 2019
HadGEM2-AO	HadGEM2	PlioMIP1	PRISM3	Tindall and Haywood 2020
HadGEM3-GC31-LL	HadGEM3	PlioMIP2	PRISM4	Presented here

554  
 555 Table 2 - Different generations of the UK physical climate model used here, and their involvement with PlioMIP  
 556

557 Multi-proxy SST data from the KM5c interglacial, compiled by McClymont *et al.* (2020), were used  
 558 for comparative purposes. Here, they focus on a narrow time-slice from 3.195 to 3.215 Ma, and  
 559 compile the SST data from two proxies: an alkenone-derived  $U^{K'}_{37}$  index (Prah1 and Wakeham, 1987)  
 560 and foraminifera calcite Mg/Ca (Delaney *et al.* 1985), with the resulting data comprising the PlioVAR  
 561 synthesis and covering 32 locations between 46°S-69°N (McClymont *et al.* 2020).

562  
 563 Maps of annual mean SST anomalies from the simulations, overlaid with the proxy data, are shown in  
 564 Figure 11 and summary statistics are shown in Table 3.

565  
 566 Figure 11 – Annual mean SST differences (Pliocene – PI) from different generations of the UK’s physical climate model. a)  
 567 HadCM3-PRISM2; b) HadCM3-PlioMIP1; c) HadCM3-PlioMIP2; d) HadGEM2; e) HadGEM3. Background gridded data

 569  
 570

	<b>HadCM3-PRISM2</b>	<b>HadCM3-PlioMIP1</b>	<b>HadCM3-PlioMIP2</b>	<b>HadGEM2</b>	<b>HadGEM3</b>
<b>Global mean (°C)</b>	1.63	1.53	1.67	2.29	3.80
<b>RMSE</b>	3.55	3.62	3.59	3.23	3.36

571  
 572 Table 3 - Global annual mean SST anomalies from Pliocene simulations using different generations of the UK’s physical  
 573 climate model, and RMSE values between simulations and SST proxy data from McClymont *et al.* (2020)  
 574  
 575  
 576

577 The global annual SST anomaly for HadGEM3 is 3.8°C, followed by HadGEM2 at 2.3°C, and then  
578 1.7°C, 1.5°C and 1.6°C for the three HadCM3 simulations (starting with the most recent, HadCM3-  
579 PlioMIP2; see Table 3). Comparing the newest model (HadGEM3) with the oldest model (HadCM3-  
580 PRISM2), which have an anomaly of 3.8°C and 1.6°C respectively, clearly the most recent generation  
581 is showing a much warmer Pliocene.

582

583 Comparing an earlier generation of the model with a later generation, but with identical boundary  
584 conditions (HadCM3-PlioMIP1 and HadGEM2, respectively; Fig. 11b and Fig. 11d), aside from the  
585 greater overall warming (2.3°C in HadGEM2 versus 1.5°C in HadCM3-PlioMIP1) already discussed  
586 above, the main spatial patterns of warming are similar, with both showing the greatest warming over  
587 the Labrador Sea and the north-west Pacific and HadGEM2 showing greater polar amplification  
588 overall. In part thanks to this high latitude warming, root mean squared error (RMSE) values are  
589 3.2°C and 3.6°C for HadGEM2 and HadCM3-PlioMIP1, respectively, showing a greater agreement  
590 between the proxy data and HadGEM2 (Table 3).

591

592 Likewise, comparing the other older model with the most recent (HadCM3-PlioMIP2 and HadGEM3,  
593 respectively; Fig. 11c and Fig. 11e), the spatial patterns of warming differ more widely, with  
594 HadGEM3 showing widespread Northern Hemisphere high latitude warming that is not shown by  
595 HadCM3-PlioMIP2 at all, other than in the Labrador Sea. HadGEM3, and indeed HadGEM2, are  
596 displaying a greater extent of polar amplification in both hemispheres (Fig. 11d-e). As the warmest  
597 model, HadGEM3 (RMSE = 3.4°C) is showing less agreement with the proxy data than HadGEM2  
598 (RMSE = 3.2°C), likely because it is so warm that the discrepancy with the colder proxy data  
599 locations (such as in the Indian Ocean, near New Zealand or off equatorial Africa) is greater (Fig.  
600 11e). This is in spite of the fact that, in the warmer proxy data locations (such as in the North Atlantic  
601 and Arctic) HadGEM3 is closer to the proxy data. In these regions, the earlier versions of the model  
602 (Fig. 11a-c) are not even capturing the sign of change and are showing a weak cooling, in stark  
603 contrast to the proxy data, that neither HadGEM2 nor HadGEM3 display (Fig. 11d-e). Where proxy  
604 data suggest colder conditions, again none of the models are capturing the sign of change and all show  
605 widespread warming, and this is most evident in HadGEM3 because of its particularly strong  
606 warming. The fact that all of the HadCM3 simulations are showing several regions of cooling and  
607 have a higher RMSE than the most recent versions suggests that this early model might be too cold.  
608 In contrast, the fact that HadGEM3 has a higher RMSE than HadGEM2 suggests that, despite  
609 involving significant model development (see Williams *et al.* 2020 for a summary), concerning  
610 Pliocene climate HadGEM3 may actually be too warm. Therefore, whilst model development appears  
611 to have improved the model's agreement with proxy data since earlier versions of the model, this only  
612 appears to be true up to a certain point; the "sweet spot" appears to be HadGEM2. Moreover, given  
613 the aforementioned point about the *mPWP* simulation not being in full equilibrium and being ~1.5°C

614 warmer if it had been (see Section 3.1.2), it is likely that both the SST anomaly and the RMSE values  
 615 would be higher when in equilibrium and therefore the performance against proxy data may be lower  
 616 than indicated here.

617

618 **4.2. Model-model comparison: HadGEM3 versus PlioMIP2 models**

619 Finally, the focus here is on mean differences, again considering SAT and precipitation anomalies,  
 620 between the *mPWP* simulation from HadGEM3 and the Pliocene simulations from all other available  
 621 models included in PlioMIP2 (Table 4).

Model, and modelling centre responsible for simulation	Spatial resolution (lon x lat)		ECS (°C)
	Atmosphere	Ocean	
CCSM4, National Centre for Atmospheric Research, US	1° x 1°	1° x 1°	3.2
CCSM4_Utr, Utrecht University, the Netherlands	2.5° x 1.9°	1° x 1°	3.2

631  
632

A number of different metrics of SAT are shown in Figure 12 for each of the models, as well as the MME; the panels shown here are updated versions of those shown in H20, but now including HadGEM3. It should be noted that, consistent with H20, the models are listed according to their published ECS, with the highest ECS listed first (see Table 4). HadGEM3 has an ECS of 5.5 K (Andrews *et al.* 2019), compared to the 2<sup>nd</sup> highest model (CESM2) with an ECS of 5.3 K (H20). If, however, all available models within CMIP6 (i.e. not just those having conducted Pliocene simulations) are considered, then HadGEM3 has the 2<sup>nd</sup> highest ECS, just below that of CanESM5 with an ECS of 5.6 K (Zelinka *et al.* 2020).

633  
634  
635

Figure 12 - SAT from Pliocene simulations from HadGEM3 and all other models in PlioMIP2. a) Global annual mean SAT (top panel) and anomalies (bottom panel); b) Extratropical (+/- 45°) annual mean SAT anomalies (top panel) and ratio (i.e.

636 >45°N divided by <45°S) between them (bottom panel); c) Land and ocean annual mean SAT anomalies, averaged globally  
637 (top panel) and between 20°N-20°S (bottom panel); d) Annual mean SAT polar amplification i.e. SAT poleward of 60°  
638 divided by global mean, for each hemisphere, where red line = ratio of 1 (i.e. no polar amplification). Figures reproduced  
639 and adapted from Haywood *et al.* (2020)

640

641 As mentioned above (Section 3.2), the global annual SAT anomaly by the end of the *mPWP*  
642 simulation is 5.1°C, making HadGEM3 one of the warmest models in PlioMIP2 and second only to  
643 CESM2 (H20). This is true both in terms of its anomaly and its mean Pliocene SAT (19°C); this is  
644 only lagging behind the warmest model by 0.2°C and 0.3°C for the anomalous and mean SAT,  
645 respectively (Fig. 12a). HadGEM3 is much warmer than earlier global annual mean temperature  
646 estimates (e.g. Haywood and Valdes 2004), and the range given by models included in PlioMIP1  
647 (1.8°C to 3.6°C, see Haywood *et al.* (2013) and PlioMIP2 (1.7°C to 5.2°C, see H20). The impact of  
648 including HadGEM3 amongst the models is to increase the MME anomaly by 0.1°C, from 3.2° to  
649 3.3°C. Interestingly the HadGEM3 *piControl\_mod* simulation is not presenting the warmest absolute  
650 PI compared to the other models, coming 4<sup>th</sup> in the list, suggesting that HadGEM3 is more sensitive to  
651 the Pliocene boundary conditions rather than being a generally warmer model overall.

652

653 Concerning annual global mean precipitation (Fig. 13, top panel), as mentioned above the  
654 precipitation anomaly by the end of the simulation is 0.34 mm day<sup>-1</sup>, making HadGEM3 not only one  
655 of the warmest models in PlioMIP2 but also one of the wettest (consistent with current understanding,  
656 as global precipitation is generally a function of global temperature). The range of anomalies across  
657 all models during PlioMIP1 was 0.09 to 0.18 mm day<sup>-1</sup> (Haywood *et al.* 2013), during PlioMIP2 it  
658 was 0.07 to 0.37 mm day<sup>-1</sup> (with the higher values being attributed to the models being more sensitive  
659 to the updated PRISM4 boundary conditions) and the PlioMIP2 ensemble mean was 0.19 mm day<sup>-1</sup>  
660 (H20). Concerning the mean, it is the wettest model in terms of both its *mPWP* (3.49 mm day<sup>-1</sup>) and  
661 *piControl\_mod* (3.15 mm day<sup>-1</sup>) simulations, and both of these are much higher than the MME (3.06  
662 mm day<sup>-1</sup> and 2.86 mm day<sup>-1</sup> for the Pliocene and PI simulations, respectively). The fact that both the  
663 HadGEM3 *mPWP* and *piControl\_mod* simulations are not only the wettest, but are also closer  
664 together in terms of mean precipitation, means that if the anomaly is considered (Fig. 13, bottom  
665 panel) HadGEM3 is not quite showing the greatest change relative to the PI; an anomaly of 0.34 mm  
666 day<sup>-1</sup> makes it 2<sup>nd</sup> only to CCSM4-Utr (at 0.37 mm day<sup>-1</sup>). The impact of including HadGEM3  
667 amongst the other PlioMIP2 models is to again slightly increase the MME anomaly, from 0.19 mm  
668 day<sup>-1</sup> as reported by H20 to 0.2 mm day<sup>-1</sup> here.

669

670 Figure 13 - Global annual mean surface precipitation (top panel) and anomalies (bottom panel) from HadGEM3 *mPWP*  
 671 simulation and all other models in PlioMIP2, as well as multi-model ensemble mean (MME). Figure reproduced and  
 672 adapted from Haywood *et al.* (2020)

673

674 If the hydrological sensitivity (i.e. the relationship between global annual mean precipitation  
 675 anomalies and SAT anomalies) of the models is considered, then in line with current understanding  
 676 (e.g. Pendergrass and Hartmann 2014). there is a clear linear relationship shown by most of the  
 677 models, with Pliocene increases in precipitation increasing in line with SAT increases (Fig. 14). This  
 678 relationship is not entirely linear, however, with the aforementioned result being shown again here i.e.  
 679 although the HadGEM3 *mPWP* simulation is the 2<sup>nd</sup> warmest of all models in PlioMIP2, it is not the  
 680 wettest, suggesting that although the model is highly sensitive to the Pliocene forcings in terms of its  
 681 temperature response, it may be less sensitive in terms of its hydrological response.

682  
 683 Figure 14 - Global annual mean surface precipitation anomalies (expressed as a percentage) versus global annual mean SAT  
 684 from HadGEM3 *mPWP* simulation, HadGEM2 and all other models in PlioMIP2  
 685

686 Returning to SAT and if only extratropical warming (separated by hemisphere, above or below 45°N  
 687 or S) is considered, then HadGEM3 agrees with the other 11 models (out of 16) that H20 identified as  
 688 showing enhanced Northern Hemisphere warming, relative to the Southern Hemisphere (Fig. 12b, top  
 689 panel). In the Northern Hemisphere, HadGEM3 is again one of the warmest models and, at 8.46°C, is  
 690 considerably warmer than most other models and the MME; this, with the inclusion of HadGEM3, has  
 691 now increased from the 5.5°C reported in H20 to 5.7°C here. However, in the Southern Hemisphere  
 692 HadGEM3 is closer to many of the other models, albeit still in the top 33% of them, and with a  
 693 warming of 6.3°C is much closer to the MME of 5.1°C (Fig. 12b, top panel). This is further  
 694 demonstrated by Fig. 12b (bottom panel), showing the ratio of warming between the hemispheres  
 695 (calculated by dividing the Northern Hemisphere warming by the Southern Hemisphere warming),  
 696 where HadGEM3 is giving a ratio of 1.34 which is again close to many of the other models and the  
 697 MME (1.17). Considering land-sea temperature contrasts (Fig. 12c), as H20 state all of the PlioMIP2  
 698 models show more warming over land, both globally and across the tropics (defined as 20°N-20°S),  
 699 and HadGEM3 is no exception. Indeed, over either land or sea, HadGEM3 is the 2<sup>nd</sup> warmest  
 700 globally and warmest across the tropics, and the inclusion of this model increases the MME by 0.1-  
 701 0.14°C depending on whether land or sea warming is considered.  
 702

703 HadGEM3 is one of the largest outliers regardless of metric, however concerning polar amplification  
 704 this is not the case. Here, as in H20, polar amplification is defined as the ratio of SAT increases  
 705 poleward of 60° divided by the global mean SAT increases (Smith *et al.* 2019), calculated  
 706 independently for each hemisphere. Despite the HadGEM3 *mPWP* simulation qualitatively showing

707 considerable amplification at both annual and seasonal timescales (Figure 7), when quantitatively  
708 compared with all other PlioMIP2 models HadGEM3 is, whilst still having amplification  $>1$  (i.e. that  
709 there is some amplification of warming around the poles), nevertheless showing considerably less  
710 amplification in both hemispheres, and is also lower than the MME in both hemispheres (Fig. 12d).  
711 Of all the models, HadGEM3 comes 4<sup>th</sup>-to-last for Northern Hemisphere amplification and last for  
712 Southern Hemisphere amplification, and its inclusion with the other models reduces the MME ratio by  
713 approximately 0.01 and 0.04 for the Northern and Southern Hemisphere, respectively. This is  
714 consistent with the conclusions of H20, who note a weak relationship between ECS and amplification;  
715 they observe that models with a lower ECS tend to display higher PA, whereas the opposite appears to  
716 be shown here i.e. HadGEM3, with one of the highest ECS, is displaying one of the lowest amounts  
717 of amplification. The amplification for all the models, as well as the MME, can be seen graphically in  
718 Figure S11 in the Supplementary Material where, at first glance, HadGEM3 would appear to be  
719 showing one of the largest amounts of amplification. However, and consistent with the observation  
720 by H20, this is because the model is showing more warming in the tropics (relative to the other  
721 models) rather than less warming at high latitudes.

722

723 Lastly, concerning SST anomalies the HadGEM3 *mPWP* simulation is warmer than most other  
724 models in PlioMIP2 (Figure 15). When simulated SST is compared to the proxy data from  
725 McClymont *et al.* (2020), if the models are ranked according to RMSE then the HadGEM3 *mPWP*  
726 simulation (RMSE = 3.4°C; see Table 3) ranks approximately halfway amongst them. There appears  
727 to be a weak relationship between the warmth of the model and agreement with proxy data, with some  
728 of the other warm models (e.g. CESM2, the warmest model) showing less agreement (RMSE =  
729 3.5°C) with the proxy data than HadGEM3; however, this is not always true, such as the case of the  
730 CCSM4-Utr which is also comparatively warm but is showing a slightly better agreement (RMSE =  
731 3.3°C) with the proxy data. It is likely that the location of the proxy data is important, as the best  
732 agreement comes from the MME (RMSE = 3.1°C) which is showing warm SST anomalies over the  
733 North Atlantic and Arctic (better in agreement with the proxy data there) but less warming relative to  
734 HadGEM3 and CESM2 in the Southern Hemisphere (better in agreement with the proxy data in e.g.  
735 the Indian Ocean).

736

737  
 738 Figure 15 – SST climatology differences (Pliocene – PI) from HadGEM3 *mPWP* simulation and all other models in  
 739 PlioMIP2, as well as multi-model ensemble mean (MME). Numbers in brackets show RMSE scores when compared proxy  
 740 data from McClymont *et al.* (2020)  
 741

742 It is likely that much of the greater warming in the HadGEM3 *mPWP* simulation, relative to the other  
 743 models, can be attributed to the relatively high ECS of this model. Figure 16 shows model ECS  
 744 against simulated Pliocene warming for all available models (see Table 4 for individual ECS values).  
 745 Also shown on this figure is the Earth System Sensitivity (ESS) which, for the Pliocene, can be taken  
 746 as the global mean temperature scaled by the CO<sub>2</sub> forcing for 560 ppmv compared with 400 ppmv.  
 747 This is because the temperature change due to the modified orography is small, and so the Pliocene  
 748 warming relative to preindustrial is due to the CO<sub>2</sub> forcing and associated feedbacks due to vegetation  
 749 and ice sheets, which can be interpreted as ESS (Lunt *et al.* 2010). Therefore, a plot of Pliocene  
 750 global mean warming against ECS will be identical to a plot of ESS against ECS, but with different  
 751 values on the y axis. There is a clear linear relationship between ECS and global mean warming (or  
 752 ESS), with the two models showing the highest ECS also having the highest Pliocene warming or ESS  
 753 (HadGEM3 and CESM2). Despite some outliers, such as CCSM4-Utr with a relatively high global

754 mean temperature anomaly but a relatively low ECS, this would suggest that for most models  
 755 Pliocene temperature anomalies (and ESS) are increasing in line with ECS.  
 756

757  
 758 Figure 16 - Global annual mean SAT anomalies versus both ESS (first y-axis) and ECS from HadGEM3 *mPWP* simulation,  
 759 HadGEM2 and all other models in PlioMIP2. The ESS axis is calculated by multiplying the global annual mean SAT  
 760 anomaly by  $\log(560/280)/\log(400/280)$  i.e. by 1.94, meaning the axis here goes from 1.94-11.64 K; for simplicity, this has  
 761 been rounded up to 2-12 K  
 762

763 **5. SUMMARY AND CONCLUSIONS**

764 This study has introduced the mid-Pliocene simulation using the latest version of the UK’s physical  
 765 climate model, HadGEM3-GC31-LL, presented the experimental design and conducted a model-  
 766 model and model-data comparison. This study is novel, being the first time this version of the UK  
 767 model has been run this far back in time; only two other paleoclimate simulations using this model  
 768 have thus far been conducted, comprising the UK’s contribution to CMIP6/PMIP4, and both of these  
 769 were more recent, Quaternary simulations (Williams *et al.* 2020).

770  
 771 The *mPWP* simulation mostly followed the experimental design defined in H16, with the exception  
 772 being the exclusion of a Pliocene LSM and Pliocene soils. Both of these were kept the same as PI.  
 773 All other boundary conditions, including CO<sub>2</sub>, orography, ice mask, lakes, vegetation fractions and  
 774 vegetation functional types followed the protocol of H16, and were incrementally implemented to be  
 775 Pliocene, based on the PRISM4 dataset. A minor model parameter change was included to increase  
 776 the model’s stability in light of the strong Pliocene forcing, and thus a corresponding PI simulation  
 777 was also run for comparison purposes. The *mPWP* simulation was run for 567 years in total, during  
 778 which atmospheric and oceanic equilibrium were assessed. Although not meeting the criteria used to  
 779 determine equilibrium in other paleoclimate simulations, especially concerning oceanic equilibrium,

780 due to computational restrictions it was not possible to run this model for the thousands of years  
781 required to achieve this.

782

783 The results presented here are divided into three sections: i) a simulation comparison, in which the  
784 *mPWP* simulation is compared to its corresponding *piControl\_mod* simulation (Section 3.2); ii) a  
785 model-model and model-data comparison, in which the most recent *mPWP* simulation is compared to  
786 Pliocene simulations from previous versions of the same model, all assessed against proxy data  
787 (Section 4.1); and iii) a model-model comparison, in which the most recent *mPWP* simulation is  
788 compared to other models (Section 4.2).

789

790 For the first comparison, the *mPWP* simulation is behaving in line with current understanding and  
791 previous work (e.g. Haywood *et al.* 2013, H20), showing a warmer and wetter world relative to the PI,  
792 with the greatest warming occurring over the poles. This polar warming, which can be attributed to a  
793 loss in sea ice and changes in clouds, and the changes to precipitation (such as an enhancement of  
794 monsoon systems) all agree with the expected response and previous work (e.g. Cronin *et al.* 1993,  
795 Howell *et al.* 2016, Li *et al.* 2018, Moran *et al.* 2006, Polyak *et al.* 2010, Zhang *et al.* 2013, 2016).  
796 For the second comparison, there is a clear increase in global temperatures (as measured by SST) as  
797 the model develops through time, beginning with the early Pliocene simulations using HadCM3 (Lunt  
798 *et al.* 2011 and Bragg *et al.* 2012), through HadGEM2 (Tindall and Haywood 2020) and up to the  
799 most recent *mPWP* simulation from HadGEM3, presented here. Up to a point, this warming results in  
800 a better agreement with available proxy data. However, just as the earlier HadCM3 simulations  
801 appear to be too cold relative to some proxy data, the most recent *mPWP* simulation from HadGEM3  
802 appears to be too warm; the “sweet spot” appears to be the previous generation of the model,  
803 HadGEM2. This would be even more the case had the *mPWP* simulation been allowed to run to full  
804 equilibrium, and it is suggested that the final global mean surface temperature could have been  
805 approximately 1.5°C higher if so. For the third comparison, the above conclusion that HadGEM3 is  
806 too warm is further suggested by the fact that it is one of the warmest and wettest models (even at its  
807 current state of equilibrium) in all of PlioMIP2 (H20), and this is true over either land or sea and  
808 especially in the Northern Hemisphere. When compared to proxy SST data, HadGEM2 ranks  
809 approximately halfway amongst the models, and is much too warm in certain locations, such as the  
810 Indian Ocean. However, the conclusion that the model is too warm overall is argued by the fact that  
811 the anomalies coming from the HadGEM3 *piControl\_mod* simulation are not the warmest, suggesting  
812 that rather than the model being too warm in general, the warming may be coming from the model’s  
813 sensitivity to the Pliocene forcing. This is consistent with the model’s high ECS, which is among the  
814 highest of all the most recent state-of-the-art CMIP6 models (Andrews *et al.* 2019, H20, Zelinka *et al.*  
815 2020).

816

817 A number of caveats should be mentioned in this study. The question over the relatively short (but  
818 unavoidable due to computational cost) run length has already been discussed, with the results  
819 suggesting that the *mPWP* simulation would have been even warmer if it had been allowed to run  
820 until true equilibrium. Besides this, firstly any differences to the PlioMIP2 models may be in part  
821 related to the fact that the LSM used here is identical to the *piControl*, rather than using the enhanced  
822 LSM following the experimental design of H16. This, as discussed above, was necessary, due to  
823 technical difficulties in coupling a new LSM to the atmosphere. One of the impacts of this is  
824 discussed in Zhang *et al.* (2021), who investigated Atlantic Meridional Overturning Circulation  
825 (AMOC) changes during the Pliocene using the PlioMIP2 models. It was found that in contrast to  
826 most other PlioMIP2 models, which stimulate a stronger AMOC in the Pliocene relative to the PI,  
827 HadGEM3 shows a weaker AMOC, with a maximum of 14.3 Sv and 16.1 Sv for the *mPWP* and  
828 *piControl\_mod* simulations, respectively (Zhang *et al.* 2021). Secondly, using PI soil parameters and  
829 soil dust properties (away from ice regions) may also have an impact on the observed warming;  
830 although H16 does provide a set of palaeosol data from Pound *et al.* (2016), this was not used here  
831 because of the difficulties in matching the reconstructions to the model's soil-related fields. Thirdly,  
832 concerning greenhouse gas forcings, in all of the Pliocene simulations discussed here only CO<sub>2</sub> was  
833 modified, with other gases such as methane being left as PI. Given that these trace gases will likely  
834 amplify warming, especially in the extratropics (Hopcroft *et al.* 2020), leaving these as PI may be  
835 resulting in a cooler climate in all of the simulations. Lastly, the large warming in the *mPWP*  
836 simulation may be because certain processes, in particular vegetation, were fixed rather than being  
837 interactive (although this is also the case in the majority of the other PlioMIP2 models). In particular,  
838 the fact that the introduction of Pliocene vegetation in the *mPWP* simulation results in such a dramatic  
839 rise in global SAT (Figure 6) deserves much further exploration. This may be highly important  
840 regarding any possible impact on the climate under a Pliocene-style forcing, and therefore current  
841 work is underway to investigate the role of vegetation in contributing to the model's simulated  
842 warming.

843

#### 844 **DATA AVAILABILITY**

845 Selected fields (SAT, precipitation and SST) from the HadGEM3 *mPWP* simulation are currently  
846 available from the Earth System Grid Federation (ESGF) WCRP Coupled Model Intercomparison  
847 Project (Phase 6), located at <https://esgf-node.llnl.gov/projects/cmip6/> (last access: 18 March 2021).  
848 If other fields are required, they can be made available to the public by directly contacting the lead  
849 author. Likewise, access to the other model simulations considered here can be gained by contacting  
850 the lead author, or the authors of the appropriate publication (see Haywood *et al.* 2020 for a list of the  
851 appropriate publications). For the SST reconstructions, the data can be found within the  
852 Supplementary Online Material of  
853 McClymont *et al.* (2020), available online at: <https://doi.org/10.5194/cp-16-1599-2020-supplement>.

854

855 **AUTHOR CONTRIBUTIONS**

856 CJRW conducted the *mPWP* simulation, carried out the analysis, produced some of the figures, wrote  
857 the majority of the manuscript, and led the paper. XR produced some of the figures. AAS, WHGR,  
858 RSS, PH and EJS provided technical assistance in running HadGEM3. JCT, SJH and AMH also  
859 provided technical assistance, and contributed the HadGEM2 and HadCM3 simulations. DJL  
860 contributed to some of the writing. All authors proofread the paper and provided comments.

861

862 **COMPETING INTERESTS**

863 The authors declare that they have no conflict of interest.

864

865 **ACKNOWLEDGEMENTS**

866 CJRW and DJL acknowledge the financial support of the UK Natural Environment Research Council  
867 (NERC)-funded SWEET project, research grant NE/P01903X/1, as well as funding from the  
868 European Research Council under the European Union's Seventh Framework Programme (FP/2007-  
869 2013)/ERC Grant Agreement no. 340923 (T-GRES). AAS was supported by the Met Office Hadley  
870 Centre Climate Programme, funded by BEIS and Defra. XR was supported by the 4D-REEF project,  
871 receiving funding from the European Union's Horizon 2020 research and innovation programme  
872 under the Marie Skłodowska-Curie research grant, no. 813360. PH was supported by a University of  
873 Birmingham Fellowship. RSS was funded by the NERC national capability grant for the UK Earth  
874 System Modelling (UKESM) project, research grant NE/N017951/1. AMH and JCT acknowledge  
875 receipt of funding from the European Research Council under the European Union's Seventh  
876 Framework Programme (FP7/2007-2013)/ERC, grant agreement no. 278636.

877

878 **FINANCIAL SUPPORT**

879 This research has been supported by the NERC-funded SWEET project (grant no. NE/P01903X/1),  
880 the Met Office Hadley Centre Climate Programme (funded by BEIS and Defra), the European Union's  
881 Horizon 2020 research and innovation programme under the Marie Skłodowska-Curie research grant  
882 (no. 813360), a University of Birmingham Fellowship, the NERC UKESM project (grant no.  
883 NE/N017951/1) and the European Union's Seventh Framework Programme (FP7/2007-2013)/ERC  
884 (grant no. 278636).

885

886 **LIST OF TABLES**

887 Table 1 - Centennial trends (calculated via a linear regression) and climatology in global mean  
888 measures of climate equilibrium over the last 50 years of the simulations, adapted from Menary *et al.*  
889 (2018) to include the CMIP6 *piControl*, *piControl\_mod* and *mPWP* simulations. Negative TOA  
890 radiation = net radiation flux is downward

891

892 Table 2 - Different generations of the UK physical climate model used here, and their involvement  
893 with PlioMIP

894

895 Table 3 - Global annual mean SST anomalies from Pliocene simulations using different generations of  
896 the UK's physical climate model, and RMSE values between simulations and SST proxy data from  
897 McClymont *et al.* (2020)

898

899 Table 4 - Climate models included here from PlioMIP2 (see Haywood *et al.* 2020 for each model's  
900 reference)

901

## 902 LIST OF FIGURES

903 Figure 1 - Changes to orography in HadGEM3 *mPWP* simulation: a) PRISM4 anomaly; b) Original  
904 field used in HadGEM3 *piControl*; c) New field used in HadGEM3 *mPWP*, with smoothed orography  
905 over western Antarctica (final version, used in simulation)

906

907 Figure 2 - Ten megabiomes from PlioMIP Phase 2 used create the nine PFTs used in HadGEM3  
908 *mPWP* simulation

909

910 Figure 3 - Nine PFTs used in HadGEM3. Top half: *piControl* simulation, bottom half: *mPWP*  
911 simulation. Values in brackets show global mean differences (*mPWP* - *piControl*), expressed as a  
912 percentage. a) broadleaf trees (18%); b) needle-leaved trees (5%); c) temperate C3 grass (-15%); d)  
913 tropical C4 grass (6%); e) shrubs (3%); f) urban areas (no change); g) inland water (1%); h) bare soil  
914 (-12%); i) land ice (-5%)

915

916 Figure 4 - LAI used in HadGEM3, for an example PFT (broadleaf trees, January). a) Function used to  
917 create LAI, where dashed lines show zonal mean from *piControl* simulation and solid lines show  
918 seasonally and latitudinally varying function of this zonal mean; b) example of functional types used  
919 in *piControl* simulation; c) same as b) but for the *mPWP* simulation

920

921 Figure 5 – Example of soil-related fields used in HadGEM3. Left-hand column: *piControl*  
922 simulation, right-hand column: *mPWP* simulation. First row: Soil parameters (example shows  
923 Volumetric soil moisture content at wilting point); Second row: Soil moisture (example shows  
924 January, top-level); Third row: Soil temperature (example shows January, top-level). Complete list of  
925 fields shown in Supplementary Material Fig. S3 and S4

926

927 Figure 6 – Annual global mean 1.5 m air temperature from the HadGEM3 *mPWP* spin-up phase and  
928 production run, as well as the CMIP6 *piControl* and the *piControl\_mod*. Labels show introduction of  
929 each new Pliocene element. Climatologies discussed here are taken from final 50 years of each  
930 simulation (shown by shaded boxes). See Williams *et al.* (2020) for the *piControl* spin-up phase that  
931 preceded these simulations.

932

933 Figure 7 – 1.5 m air temperature climatology differences (*mPWP* – *piControl\_mod*) from HadGEM3.  
934 a) Annual; b) DJF; c) JJA

935

936 Figure 8 – Sea ice fraction climatology differences (*mPWP* – *piControl\_mod*) from HadGEM3: a)  
937 Northern Hemisphere DJF, b) Northern Hemisphere JJA, c) Southern Hemisphere DJF, d) Southern  
938 Hemisphere JJA, e) Mean sea ice area (both absolute values and differences) averaged over either  
939 hemisphere

940

941 Figure 9 – Surface precipitation climatology differences (*mPWP* – *piControl\_mod*) from HadGEM3.  
942 a) Annual; b) DJF; c) JJA

943

944 Figure 10 – Total cloud fraction climatology differences (*mPWP* – *piControl\_mod*) from HadGEM3.  
945 a) Annual; b) DJF; c) JJA

946

947 Figure 11 – Annual mean SST differences (Pliocene – PI) from different generations of the UK's  
948 physical climate model. a) HadCM3-PRISM2; b) HadCM3-PlioMIP2; c) HadCM3-PlioMIP2; d)  
949 HadGEM2; e) HadGEM3. Background gridded data shows model simulations, filled circles show  
950 SST proxy data from McClymont *et al.* (2020)

951

952 Figure 12 - SAT from Pliocene simulations from HadGEM3 and all other models in PlioMIP2. a)  
953 Global annual mean SAT (top panel) and anomalies (bottom panel); b) Extratropical (+/- 45°) annual  
954 mean SAT anomalies (top panel) and ratio (i.e. >45°N divided by <45°S) between them (bottom  
955 panel); c) Land and ocean annual mean SAT anomalies, averaged globally (top panel) and between  
956 20°N-20°S (bottom panel); d) Annual mean SAT polar amplification i.e. SAT poleward of 60°  
957 divided by global mean, for each hemisphere, where red line = ratio of 1 (i.e. no polar amplification).  
958 Figures reproduced and adapted from Haywood *et al.* (2020)

959

960 Figure 13 - Global annual mean surface precipitation (top panel) and anomalies (bottom panel) from  
961 HadGEM3 *mPWP* simulation and all other models in PlioMIP2, as well as multi-model ensemble  
962 mean (MME). Figure reproduced and adapted from Haywood *et al.* (2020)

963

964 Figure 14 - Global annual mean surface precipitation anomalies (expressed as a percentage) versus  
965 global annual mean SAT from HadGEM3 *mPWP* simulation, HadGEM2 and all other models in  
966 PlioMIP2

967

968 Figure 15 – SST climatology differences (Pliocene – PI) from HadGEM3 *mPWP* simulation and all  
969 other models in PlioMIP2, as well as multi-model ensemble mean (MME). Numbers in brackets  
970 show RMSE scores when compared proxy data from McClymont *et al.* (2020)

971

972 Figure 16 - Global annual mean SAT anomalies versus both ESS (first y-axis) and ECS from  
973 HadGEM3 *mPWP* simulation, HadGEM2 and all other models in PlioMIP2. The ESS axis is  
974 calculated by multiplying the global annual mean SAT anomaly by  $\log(560/280)/\log(400/280)$  i.e. by  
975 1.94, meaning the axis here goes from 1.94-11.64 K; for simplicity, this has been rounded up to 2-12  
976 K

977
